Table of Contents

1. INTRODUCTION.....	1-1
1.1 SUMMARY	1-1
1.2 FEATURES	1-3
1.3 TECHNICAL DESCRIPTION	1-4
2. HARDWARE INTERFACE.....	2-1
2.1 HARDWARE INTERFACE SIGNAL DESCRIPTION	2-1
2.2 LINE TRANSFORMER REQUIREMENTS FOR K56flex, V.34/V.32	2-20
3. SOFTWARE INTERFACE	3-1
3.1 INTERFACE MEMORY	3-1
3.1.1 Interface Memory Map	3-1
3.1.2 Interface Memory Signal Definitions	3-1
4. DSP RAM ACCESS.....	4-1
4.1 INTERFACE MEMORY ACCESS TO DSP RAM	4-1
4.1.1 RAM Access Methods	4-1
4.1.2 RAM Parameters	4-1
4.2 HOST DSP READ AND WRITE PROCEDURES	4-5
4.3 RAM READ AND WRITE EXAMPLES	4-5
4.4 DSP RAM DATA SCALING	4-10
5. HDLC OPERATION	5-1
5.1 HDLC FRAMES	5-1
5.2 HDLC AND FIFO DATA BUFFERS	5-2
5.2.1 Transmit and Receive FIFO Data Buffers	5-2
5.2.2 RX FIFO and HDLC Operation	5-2
5.3 OPERATION	5-4
5.3.1 Transmitter and Receiver Setup	5-4
5.3.2 Transmitter HDLC Operation	5-5
5.3.3 Receiver HDLC Operation	5-5
5.4 EXAMPLE APPLICATION	5-6
5.4.1 Transmitter Example (Tx FIFO Disabled)	5-6
5.4.2 Transmitter Example (Tx FIFO Enabled)	5-6
5.4.3 Receiver Example	5-7
6. HOST FUNCTIONS	6-1
6.1 INTERRUPT REQUEST HANDLING	6-1
6.2 AUTO DIAL PROCEDURE	6-1
6.3 AUTO MODE DETECTION	6-1
6.4 MODEM SELF-TEST INFORMATION	6-6
6.4.1 Controller Self-Test	6-6
6.4.2 DSP Self-Test	6-6
6.5 EQM AVERAGING	6-8

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

6.6	RETRAIN AND AUTOMATIC RATE CHANGE.....	6-9
6.6.1	Retrain Without a Rate Change	6-9
6.6.2	Retrain With a Rate Change	6-9
6.7	HANDSHAKE TIME-OUT TIMERS.....	6-9
6.8	CLEARDOWN	6-10
6.8.1	V.90 Cleardown.....	6-10
6.8.2	K56flex Cleardown	6-10
6.8.3	V.34 Cleardown.....	6-10
6.8.4	V.32 bis Cleardown	6-10
7.	DESIGN CONSIDERATIONS	7-1
7.1	PC BOARD LAYOUT GUIDELINES	7-1
7.2	ELECTROMAGNETIC INTERFERENCE (EMI) CONSIDERATIONS	7-3
7.3	CRYSTAL SPECIFICATIONS	7-5
7.4	INTERFACE CIRCUITS	7-7
7.5	PACKAGE DIMENSIONS.....	7-9

1. INTRODUCTION

1.1 SUMMARY

The Rockwell RP56LD/RP336LD and RP56D/RP336D Modem Data Pump (MDP) families support high speed data, high speed fax, AudioSpan, voice coding/decoding, full-duplex speakerphone (optional), and AudioSpan (optional) functions depending upon model (Table 1-1). The RP56D/RP336D, with low voltage operation and small footprint support desktop applications. The RP56LD/RP336LD, with low voltage operation and low power consumption support portable applications. Downloadable architecture allows upgrading of MDP code from the host/DTE. The RP56LD/RP56D supports ITU-T V.90, K56flex™, and V.34 data modem operation. The RP336LD/RP336D supports V.34 data modem operation. Other than power consumption, models of the RP56LD/RP336LD are identical to like models of the RP56D/RP336D. Other than not supporting V.90, RP336LD/RP336D are identical to corresponding RP56LD/RP56D models.

V.90/K56flex MDPs can receive data at speeds up to 56 kbps from a digitally connected V.90- or K56flex-compatible central site modem. These MDPs take advantage of the PSTN which is primarily digital except for the client modem to central office local loop and are ideal for applications such as remote access to an Internet service provider (ISP), on-line service, or corporate site. The MDP can send upstream data at speeds up to V.34 rates.

In V.34 data mode, the MDP can operate in 2-wire, full-duplex, synchronous/asynchronous modes at rates up to 33600 bps. Using V.34 techniques to optimize modem configuration for line conditions, the MDP can connect at the highest data rate that the channel can support from 33600 bps to 2400 bps with auto-fallback to V.32 bis.

Internal HDLC support eliminates the need for an external serial input/output (SIO) device in the DTE for products incorporating error correction and T.30 protocols.

Voice mode includes an Adaptive Differential Pulse Code Modulation (ADPCM) voice coder and decoder (codec). The codec compresses and decompresses voice signals for efficient digital storage of voice messages. The codec operates at 28.8k, 21.6k, or 14.4k bps (4-bit, 3-bit, or 2-bit quantization, respectively) with a 7.2 kHz or 8.0 kHz sample rate.

A voice pass-through mode allows the host to transmit and receive uncompressed voice samples in 16-bit linear form at 7.2 kHz, 8.0 kHz, or 11.025 kHz sample rate, or in 8-bit A-Law/μ-Law PCM form at 8.0 kHz sample rate.

SP models support position-independent full-duplex speakerphone (FDSP) operation using a dual internal integrated analog circuit to interface with the telephone line and the audio input/out (i.e., a headset, handset, or a microphone with external speaker).

144-pin TQFP models also support a 4-line voice serial interface used to transfer 16-bit linear or 8-bit A-Law/μ-Law PCM FDSP voice samples with acoustic echo cancellation to and from the host. This interface can be used by the host to support concurrent voice and data modem applications such as host-based DSVD.

AudioSpan (analog simultaneous audio/voice and data) operation supports at a data rate of 4.8 kbps.

The MDP operates over the public switched telephone network (PSTN) through the appropriate line termination.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Table 1-1. Modem Models and Functions

Modem/Part Number ¹		Package and Package Options			Supported Functions ²			
Model Number	Part No.	Package	Crystal/Clock Input	Analog Interface Voltage	V.90/K56flex Data	V.34 Data, V.34 Fax, Voice/Audio, AudioSpan	FDSP	Voice Serial Interface

Notes:

1. Model/part number options:

- L Low power
- D Downloadable
- SP Speakerphone.

2. Supported functions (Y = Supported; – = Not supported):

- FDSP Full-duplex speakerphone
- Voice/Audio Voice and audio
- AudioSpan Analog simultaneous voice and data.

1.2 FEATURES

- Downloadable MDP code from the host/DTE
- 2-wire full-duplex
 - ITU-T V.90 and K56flex (RP56 models), V.34 (33.6 kbps), V.32 bis, V.32, V.22 bis, V.22, V.23, and V.21
 - Bell 212 and 103
- 2-wire half-duplex
 - ITU-T V.34 fax, V.17, V.33, V.29, V.27 ter, and V.21 channel 2
 - Bell 208
 - Short train option in V.17 and V.27 ter
- Serial synchronous and asynchronous data
- Parallel synchronous and asynchronous data
- Parallel synchronous SDLC/HDLC support
- In-band secondary channel (V.34 and V.32 bis)
- Automatic mode selection (AMS)
- Automatic rate adaption (ARA)
- Digital near-end and far-end echo cancellation
- Bulk delay for satellite transmission
- Auto-dial and auto-answer
- ADPCM voice mode (7.2 kHz or 8.0 kHz)
- Voice pass-through mode (7.2 kHz, 8.0 kHz, or 11.025 kHz)
- Full-duplex speakerphone (SP models)
 - Acoustic and line echo cancellation
 - Programmable microphone AGC
 - Microphone volume selection and muting
 - Speaker volume control and muting; room monitor
- Voice serial data interface (144-pin TQFP)
 - 16-bit linear or 8-bit A-Law/ μ -Law PCM voice samples
 - FDSP support with acoustic echo cancellation
- AudioSpan
 - ITU-T V.61 modulation (4.8 kbps data plus audio)
 - Handset, headset, or half-duplex speakerphone
- TTL and CMOS compatible DTE interface
 - ITU-T V.24 (EIA/TIA-232-E) (data/control)
 - Microprocessor bus (data/configuration/control)
- Dynamic range: -9 dBm to -43 dBm
- Adjustable speaker output to monitor received signal
- DMA support interrupt lines
- Transmit and receive (16+128)-byte FIFO data buffers for burst data transfer
- NRZI encoding/decoding
- 511 pattern generation/detection
- V.8 and V.8 bis signaling
- V.13 signaling
- Diagnostic capability
 - V.54 inter-DCE signaling
 - V.54 local analog and remote digital loopback
- +3.3V operation with +5V tolerant inputs
 - +5V or +3.3V analog signal interface
- Low profile, small footprint package meets PCMCIA Type II envelope requirements for PC Cards
 - 100-pin PQFP or 144-pin TQFP

1.3 TECHNICAL DESCRIPTION

Configurations and Rates

The selectable MDP configurations, signaling rates, and data rates are listed in Table 1-2.

Automatic Mode Selection

When automatic mode selection (AMS) is enabled, the MDP configures itself to the highest compatible data rate supported by the remote modem (AUTO bit). Automode operation is supported in V.90, K56flex, V.34, V.32 bis, V.32 V.22 bis, V.22, V.21, V.23, Bell 212A, and Bell 103 modes.

NOTE: Bit names refer to data, control, and/or status bits in the MDP interface memory (see Table 3-1).

Automatic Rate Adaption (ARA)

In K56flex, V.34, and V.32 bis modes, automatic rate adaption (ARA) can be enabled to select the highest data rate possible based on the measured eye quality monitor (EQM) (EARC bit). This selection occurs during handshake/retrain and rate renegotiation.

Tone Generation

The MDP can generate single or dual voice-band tones from 0 Hz to 3600 Hz with a resolution of 0.15 Hz and an accuracy of $\pm 0.01\%$. Tones over 3000 Hz are attenuated. DTMF tone generation allows the MDP to operate as a programmable DTMF dialer.

Data Encoding

The data encoding conforms to ITU-T recommendations V.90, V.34, V.32 bis, V.32, V.17, V.33, V.29, V.27 ter, V.22 bis, V.22, V.23, or V.21, and is compatible with Bell 208, 212A, or 103, depending on the configuration.

RTS - CTS Response Time

The response times of CTS relative to a corresponding transition of RTS are listed Table 1-3.

Transmit Level

The transmitter output level is selectable from -4 dBm to -19 dBm (VAA = +3.3V) or 0 dBm to -15 dBm (VAA = +5V) in 1 dB steps and is accurate to ± 0.5 dB when used with an external hybrid. The output level can also be fine tuned by changing a gain constant in MDP DSP RAM. The maximum V.34/V.32 bis/V.32 transmit level for acceptable receive performance should not exceed -9 dBm.

Note: In V.34 mode, the transmit level may be automatically changed during the handshake. This automatic adjustment of the transmit level may be disabled via a parameter in DSP RAM.

Transmitter Timing

Transmitter timing is selectable between internal ($\pm 0.01\%$), external, or slave.

Scrambler/Descrambler

A self-synchronizing scrambler/descrambler is used in accordance with the selected configuration.

Answer Tone

When the NV25 bit is a zero, the MDP generates a 2100 Hz answer tone at the beginning of the answer handshake for 5.0 seconds (V.8) or 3.6 seconds (V.32 bis, V.32, V.22 bis, V.22, V.23, and V.21). The answer tone has 180° phase reversals every 0.45 second to disable network echo cancellers (V.8, V.32 bis, V.32).

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Table 1-3. RTS-CTS Response Times

Configuration	RTS-CTS Response ¹		Turn-Off Sequence ³
	Constant Carrier	Controlled Carrier	
V.90, K56flex, V.34, V.32 bis, V.32	± 2 ms	N/A	N/A
V.33/V.17 Long	N/A	1393 ms ²	15 ms ⁴
V.33/V.17 Short	N/A	142 ms ²	15 ms ⁴
V.29	N/A	253 ms ²	12 ms
V.27 4800 Long	N/A	708 ms ²	7 ms ⁴
V.27 4800 Short	N/A	50 ms ²	7 ms ⁴
V.27 2400 Long	N/A	943 ms ²	10 ms ⁴
V.27 2400 Short	N/A	67 ms ²	10 ms ⁴
V.22 bis, V.22, Bell 212A	± 2 ms	270 ms	N/A
V.21	500 ms	500 ms	N/A
V.23, Bell 103	210 ms	210 ms	N/A
Notes: <ol style="list-style-type: none"> 1. Times listed are CTS turn-on. The CTS OFF-to-ON response time is host programmable in DSP RAM. (Full-duplex modes only.) 2. Add echo protector tone duration plus 20 ms when echo protector tone is used during turn-on. 3. Turn-off sequence consists of transmission of remaining data and scrambled ones for controlled carrier operation. CTS turn-off is less than 2 ms for all configurations. 4. Plus 20 ms of no transmitted energy. 5. N/A = not applicable. 			

Receive Level

The MDP satisfies performance requirements for received line signal levels from –9 dBm to –43 dBm measured at the Receiver Analog (RXA) (TIP and RING) input (–15 dBm at RIN).

Note: A 6 dB pad is required between TIP and RING and the RIN input.

Receiver Timing

The timing recovery circuit can track a frequency error in the associated transmit timing source of ±0.035% (V.22 bis) or ±0.01% (other configurations).

Carrier Recovery

The carrier recovery circuit can track a ±7 Hz frequency offset in the received carrier.

Clamping

Received Data (RXD) is clamped to a constant mark whenever the Received Line Signal Detector (~RLSD) is off. ~RLSD can be clamped off (RLSDE bit).

Echo Canceller

A data echo canceller with near-end and far-end echo cancellation is included for 2-wire full-duplex V.34/V.32 bis/V.32 operation. The combined echo span of near and far cancellers can be up to 40 ms. The proportion allotted to each end is automatically determined by the MDP. The delay between near-end and far-end echoes can be up to 1.2 seconds.

V.90 and K56flex echo cancellation is also provided.

ADPCM Voice Mode

The Adaptive Differential Pulse Code Modulation (ADPCM) voice coder and decoder (codec) compresses and decompresses voice signals for efficient digital storage of voice messages. The codec operates at 28.8k, 21.6k, or 14.4k bps (4-bit, 3-bit, or 2-bit quantization, respectively) with a 7.2 kHz or 8.0 kHz sample rate.

Transmit Voice. 16-bit compressed transmit voice can be sent to the MDP ADPCM codec for decompression then to the digital-to-analog converter (DAC) by the host.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Receive Voice. 16-bit received voice samples from the MDP analog-to-digital converter (ADC) can be sent to the ADPCM codec for compression, and then be read by the host.

Voice Pass-Through Mode

Voice pass-through mode allows the host to transmit and receive uncompressed voice samples in 16-bit linear form at 7.2 kHz, 8.0 kHz, or 11.025 kHz sample rate, or in 8-bit A-Law/ μ -Law PCM form at 8.0 kHz sample rate.

Transmit Voice. Transmit voice samples can be sent to the MDP DAC from the host.

Receive Voice. Received voice samples from the MDP ADC can be read by the host.

Voice/Audio Paths

The MDP incorporates a dual integrated analog interface. The voice/audio transmit and receive signals can be routed through several paths. The voice/audio paths are available in the speakerphone mode configuration and are selected through DSP RAM.

The voice/audio input can be taken from one of four different sources: telephone line input (RIN), handset (TELIN), microphone (MICM or MICV).

The speaker output (SPK) can originate from one of five different sources: RIN, TELIN, MICM or MICV or from the MDP's internal voice playback mode.

The voice/audio output may be routed to the telephone line output (TXA1 and TXA2) or handset (TELOUT).

The voice paths can be switched to allow an audio input to be routed to the telephone line output through a variable gain for applications such as music-on-hold.

The "room monitor" mode allows the MDP to receive audio from its surroundings and concurrently transmit the audio to a remote site.

Voice Serial Interface (144-Pin TQFP)

A 4-pin serial interface supports the transfer of 16-bit linear or 8-bit A-Law/ μ -Law PCM voice samples in full-duplex speakerphone form with acoustic echo cancellation to and from the host. These signals can be used in concurrent voice and data applications such as host-controlled DSVD by the host. Signals supported are Serial Data Output (S8OUT), Serial Data In (SR8IN), Serial Shift Clock (SR4CLK), and Sample Shift Clock (SA4CLK).

Analog voice on the MICV input pin is converted to 16-bit linear or 8-bit A-Law/ μ -Law PCM digital voice samples and output on the SR8OUT pin to the host. Digital voice in 16-bit linear or 8-bit A-Law/ μ -Law PCM form is received from the host on the SR8IN pin, converted to analog form and routed to the SPK output pin. SA4CLK provides the bit clock used to shift data bits in on the SR8IN pin and out on the SR8OUT pin. SR8CLK provides the frame clock used to synchronize words shifted in on the SR8IN pin and shifted out on the SR8OUT pin.

AudioSpan Mode

AudioSpan provides full-duplex analog simultaneous audio/voice and data over a single telephone line at a data rate with audio of 4800 bps using V.61 modulation. AudioSpan can send any type of audio waveform, including music. Data can be sent with or without error correction. The audio/voice interface can be in the form of a headset, handset, or a microphone and speaker (half-duplex speakerphone). Handset echo cancellation is provided.

Data Formats

Serial Synchronous Data

Data rate: 300-33600 (RP336) or 300-56000 (RP56) bps $\pm 0.01\%$.

Selectable clock: Internal, external, or slave.

Serial Asynchronous Data

Data rate: 300-33600 (RP336) or 300-56000 (RP56) bps $\pm 0.01\%$.

0-300 bps (V.21 and Bell 103);

1200/75 bps (V.23).

Bits per character: 7, 8, 9, 10, or 11.

Parallel Synchronous Data

Normal sync: 8-bit data for transmit and receive

Data rate: 300-33600 (RP336) or 300-56000 (RP56) bps $\pm 0.01\%$.

SDLC/HDLC support:

Transmitter: Flag generation, 0 bit stuffing, CRC-16 or CRC-32 generation.

Receiver: Flag detection, 0 bit deletion, CRC-16 or CRC-32 checking.

Parallel Asynchronous Data

Data rate: 300-33600 (RP336) or 300-56000 (RP56) bps $+1\%$ (or 2.3%), -2.5% ;
1200, 300, or 75 bps (FSK).

Data bits per character: 5, 6, 7, or 8.

Parity generation/checking: Odd, even, or 9th data bit.

Async/Sync and Sync/Async Conversion

An asynchronous-to-synchronous converter is provided in the transmitter and a synchronous-to-asynchronous converter is provided in the receiver. The converters operate in both serial and parallel modes. The asynchronous character format is 1 start bit, 5 to 8 data bits, an optional parity bit, and 1 or 2 stop bits. Valid character size, including all bits, is 7, 8, 9, 10, or 11 bits per character. Two ranges of signaling rates are provided:

- Basic range: $+1\%$ to -2.5%
- Extended overspeed range: $+2.3\%$ to -2.5%

When the transmitter's converter is operating at the basic signaling rate, no more than one stop bit will be deleted per 8 consecutive characters. When operating at the extended rate, no more than one stop bit will be deleted per 4 consecutive characters. Break handling is performed as described in V.14.

Asynchronous characters are accepted on the TXD serial input and are issued on the RXD serial output.

V.54 Inter-DCE Signaling

The MDP supports V.54 inter-DCE signaling procedures in synchronous and asynchronous configurations. Transmission and detection of the preparatory, acknowledgment, and termination phases as defined in V.54 are provided. Three control bits in the transmitter allow the host to send the appropriate bit patterns (V54T, V54A, and V54P bits). Three control bits in the receiver are used to enable one of three bit pattern detectors (V54TE, V54AE, and V54PE bits). A status bit indicates when the selected pattern detector has found the corresponding bit pattern (V54DT bit).

V.13 Remote RTS Signaling

The MDP supports V.13 remote RTS signaling. Transmission and detection of signaling bit patterns in response to a change of state in the RTS bit or the \sim RTS input signal are provided. The RRTSE bit enables V.13 signaling. The RTSDE bit enables detection of V.13 patterns. The RTSST status bit indicates the state of the remote RTS signal. This feature may be used to clamp/unclamp the local \sim RLSD and RXD signals in response to a change in the remote RTS signal in order to simulate controlled carrier operation in a constant carrier environment. The MDP automatically clamps and unclamps \sim RLSD.

Dialing and Answering

The host can dial and answer using supported DTMF dialing and tone detection functions. The major parameters are host programmable.

Supervisory Tone Detection

Three parallel tone detectors (A, B, and C) are provided for supervisory tone detection. The signal path to these detectors is separate from the main received signal path.

Each tone detector consists of two cascaded second order IIR biquad filters. The coefficients are host programmable. Each fourth order filter is followed by a level detector which has host programmable turn-on and turn-off thresholds allowing hysteresis. Tone detector C is preceded by a prefilter and squarer. This circuit is useful for detecting a tone with frequency equal to the difference between two tones that may be simultaneously present on the line. The squarer may be disabled by the SQDIS bit causing tone detector C to be an eighth order filter. The tone detectors are disabled in data mode.

The tone detection sample rate is 9600 Hz in V.8 and is 7200 Hz in other modes. The default call progress filter coefficients are based on a 7200 Hz sampling rate and apply to non-V.34 modes only. The maximum detection bandwidth is equal to one-half the sample rate. The tone detection sample rate can 7200 Hz or 8000 Hz in voice mode (CONF ACh). The default bandwidths and thresholds of the tone detectors are:

Tone Detector	Bandwidth	Turn-On Threshold	Turn-Off Threshold
A	245 – 650 Hz	–25 dBm	–31 dBm
B	360 – 440 Hz	–25 dBm	–31 dBm
C Prefilter	0 – 500 Hz	N/A	N/A
C	50 – 110 Hz	*	*
* Tone Detector C will detect a difference tone within its bandwidth when the two tones present are in the range –1 dBm to –26 dBm.			

511 Pattern Generation/Detection

In synchronous mode, a 511 pattern can be generated and detected (control bit S511). Use of this bit pattern during self-test eliminates the need for external test equipment.

In-Band Secondary Channel

A full-duplex in-band secondary channel is provided in V.34 (all speeds) and V.32 bis/V.32 (7200 bps and above) modes. Control bit SECEN enables and disables the secondary channel operation. The secondary channel operates in parallel data mode with independent transmit and receive interrupts and data buffers. The main channel may operate in parallel or serial mode.

In V.34 modes, the secondary channel rate is 200 bps.

In V.32 bis/V.32 modes, the secondary channel rate is 150 bps. This rate is also host programmable in V.32 bis/V.32 modes.

Transmit and Receive FIFO Data Buffers

Two (16+128)-byte first-in first-out (FIFO) data buffers allow the DTE/host to rapidly output up to 144 bytes of transmit data and input up to 144 bytes of accumulated received data. The receiver FIFO is always enabled. The transmitter FIFO is enabled by the FIFOEN control bit. TXHF and RXHF bits operate off the lower 16 bits and indicate the corresponding FIFO buffer half full (8 or more bytes loaded) status. TXFNF and RXFNE bits indicate the TXFIFO buffer not full and RXFIFO buffer not empty status, respectively. An interrupt mask register allows an interrupt request to be generated whenever the TXFNF, RXFNE, RXHF, or TXHF status bit changes state. The 128-byte FIFO extensions are enabled by default and can be disabled by clearing a bit in RAM. (See Section 4, Function 74.)

DMA Support Interrupt Request Lines

DMA support is available in synchronous, asynchronous, and HDLC parallel data modes. Control bit DMAE enables and disables DMA support. When DMA support is enabled, the MDP ~RI and ~DSR lines are assigned to Transmitter Request (TXRQ) and Receiver Request (RXRQ) hardware output interrupt request lines, respectively. The TXRQ and RXRQ signals follow the assertion of the TDBE and RDBF interrupt bits thus allowing the DTE/host to respond immediately to the interrupt request without masking out status bits to determine the interrupt source.

NRZI Encoding/Decoding

NRZI data encoding/decoding may be selected in synchronous and HDLC modes instead of the default NRZ (control bit NRZIEN). In NRZ encoding, a 1 is represented by a high level and a 0 is represented by a low level. In NRZI encoding, a 1 is represented by no change in level and a 0 is represented by a change in level.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

ITU-T CRC-32 Support

ITU-T CRC-32 generation/checking may be selected instead of the default ITU-T CRC-16 in HDLC mode using DSP RAM access.

Caller ID Demodulation

Caller ID information can be demodulated in V.23 1200 receive configuration and presented to the host/DTE in serial (RXD) and parallel (RBUFFER) form.

Relay Control. Direct control of the off-hook and talk/data relays is provided. Internal relay drivers allow direct connection to the off-hook (RLYA) and talk/data (RLYB) relays. The talk/data relay output can optionally be used for pulse dial.

Speaker Interface

An analog speaker output (SPK) is provided with on/off and volume control logic incorporated in the MDP. An external amplifier is recommended if driving non-amplified speakers.

A digital speaker output (SPKMD) is provided which reflects the received analog input signal digitized to TTL high or low level by an internal comparator to create a PC Card (PCMCIA)-compatible signal. See the VOLUME bits description in Section 3.

2. HARDWARE INTERFACE

2.1 HARDWARE INTERFACE SIGNAL DESCRIPTION

A functional interconnect diagram showing the typical MDP connection in a system is illustrated in Figure 2-1. Any point that is active low is represented by a small circle at the signal point.

Edge triggered inputs are denoted by a small triangle (e.g., TDCLK). An active low signal is indicated by a tilde preceding the signal name (e.g., ~RESET).

A clock intended to activate logic on its rising edge (low-to-high transition) is called active low (e.g., ~RDCLK), while a clock intended to activate logic on its falling edge (high-to-low transition) is called active high (e.g., TDCLK). When a clock input is associated with a small circle, the input activates on a falling edge. If no circle is shown, the input activates on a rising edge.

The 144-pin TQFP MDP hardware interface signals are shown Figure 2-2.

The 144-pin TQFP MDP signal pin assignments are shown Figure 2-3 and are listed in Table 2-1.

The 100-pin PQFP MDP hardware interface signals are shown Figure 2-4.

The 100-pin PQFP MDP signal pin assignments are shown Figure 2-5 and are listed in Table 2-2.

The MDP hardware interface signals are described in Table 2-3.

The digital interface characteristics are defined in Table 2-4.

The analog interface characteristics are defined Table 2-5.

The power requirements are defined in Table 2-6.

The absolute maximum ratings are defined in Table 2-7.

The timing for DTE host microprocessor interface bus waveforms is shown in Table 2-8.

The host bus waveforms are illustrated in Figure 2-6.

The DTE serial interface waveforms are illustrated in Figure 2-7.

 - DTE = Data Terminal Equipment
 - PIF = Parallel host interface
 - SIF = Serial DTE interface.
- 4. Package option.

Table 2-3. MDP Signal Definitions

Label	I/O Type	Signal/Definition																				
OVERHEAD SIGNALS																						
CLKIN	IA	Clock In (144-Pin TQFP). If external clock is selected (NOXTL = low), connect to an external 56.448 MHz or 28.224 MHz clock circuit. The clock frequency is selected by the MK4 and MK5 inputs.																				
XTLI	I	Crystal In (144-Pin TQFP). If external crystal is selected (NOXTL = high), connect to an external 56.448 MHz or 28.224 MHz crystal circuit. The clock frequency is selected by the MK4 and MK5 inputs.																				
XTLO	O	Crystal Out (144-Pin TQFP). If external crystal is selected (NOXTL = high), connect to the external crystal circuit return.																				
NOXTL	IA	No Crystal Circuit (144-Pin TQFP). Selects external crystal (NOXTL = high, i.e., leave open or connect to VDD through 10kΩ) or clock (NOXTL = low, i.e., connect to GND) circuit. Internal pull-up provided.																				
XTLI/CLKIN	I	Crystal In/Clock In (100-Pin PQFP). Connect to an external 56.448 MHz/28.224 MHz crystal circuit (crystal input option) or to an external 56.448 MHz/28.224 MHz clock circuit (clock input option).																				
XTLO/NC	O	Crystal Out/NC (100-Pin PQFP). Connect to the external crystal circuit return (crystal input option) or leave open (clock input option).																				
~RES1, ~RES2	IA	Reset. ~RESET low holds the MDP in the reset state. ~RESET going high releases the MDP from the reset state and initiates normal operation using power turn-on (default) values. ~RESET must be held low for at least 3 μs. The MDP is ready to use 400 ms after the low-to-high transition of ~RESET. ~RES1 and ~RES2 are typically connected to the MCU ~RESET input and to the host bus ~RESET (or RESET through an inverter) line (parallel host) or reset circuit (serial DTE interface) which resets both the MCU and MDP upon power turn-on. ~RES1 and ~RES2 have active internal pull-up resistors.																				
~WKRES	IA	Wake-up Reset. ~WKRES is connected internally to ~RESET but will not drive the MDP ~RESET pins. Asserting ~WKRES performs the same reset function as the MDP ~RESET and typically used by the MCU to wake up the MDP from SLEEP Mode when the MDP ~RESET lines cannot be asserted (because they are also connected to the MCU ~RESET input). For a serial DTE or parallel host MCU configuration, connect ~WKRES to the MCU ~WKRESOUT output. ~WKRES has an active internal pull-up resistor.																				
VDD	PWR	+3.3V Digital Circuit Power Supply. Connect to +3.3V through digital circuit power supply filter.																				
AVDD	PWR	+3.3V Analog Circuit Digital Power Supply. Connect to +3.3V through digital circuit power supply filter																				
AVAA	PWR	Analog Circuit Analog Power Supply. Connect to +3.3V or +5V (preferred) through analog circuit power supply filter. Note: When operating the analog circuitry at +3.3V, the transmit level is 4 dB lower and the converted receive level is 4 dB higher when compared to operating the analog circuitry at +5V. The transmit level must be adjusted accordingly using TLVL or other means.																				
VGG	REF	Input Reference Voltage. Reference voltage for +5V tolerant input pins. Connect to the highest of +3.3V or +5V available on the circuit board. A connection to +5V allows +5V or +3.3V input levels. A connection to +3.3V allows +3.3V input levels only.																				
GND	GND	Digital Ground. Connect to digital ground.																				
AGND	GND	Analog Ground. Connect to analog ground.																				
~SET3V	IA	Set Integrated Analog +3.3V Reference. Selects analog circuit voltage reference: High (NC) = +5V, low (AGND) = +3.3V.																				
MK4	IA	PLL Circuit Enable/Disable (144-Pin TQFP). This pin disables (MK4 = high) or enables (MK4 = low, recommended setting) the internal PLL circuit. Connect this pin to GND to enable the PLL circuit. Internal pull-up provided. MK4 must be low if using the 28.224 MHz option. See MK5. Note: The 100-pin PQFP is internally bonded to enable the internal PLL.																				
MK5	IA	PLL Circuit Frequency Select (144-Pin TQFP). This pin selects the input frequency (MK5 high = 28.224 MHz, MK5 low = 56.448 MHz) when the internal PLL circuit is enabled (MK4 = low). If the PLL is disabled (MK4 = high), leave MK5 high and use 56.448 MHz. Internal pull-up provided. See MK4. If 28.224 MHz input frequency is used, MK4 must be low and MK5 must be high. Note: The 100-pin PQFP is internally bonded to select a 28.224 MHz input frequency. <table><tr><th>MK4</th><th>MK5</th><th>PLL Enabled</th><th>Crystal/Clock</th></tr><tr><td>0</td><td>0</td><td>Yes</td><td>56.448 MHz</td></tr><tr><td>0</td><td>1</td><td>Yes</td><td>28.224 MHz (Most common)</td></tr><tr><td>1</td><td>0</td><td>No</td><td>Invalid Option</td></tr><tr><td>1</td><td>1</td><td>No</td><td>56.448 MHz</td></tr></table>	MK4	MK5	PLL Enabled	Crystal/Clock	0	0	Yes	56.448 MHz	0	1	Yes	28.224 MHz (Most common)	1	0	No	Invalid Option	1	1	No	56.448 MHz

1	1	No	56.448 MHz																			

Table 2-3. MDP Signal Definitions (Cont'd)

Label	I/O Type	Signal Name/Description
OVERHEAD SIGNALS (CONTINUED)		
XCLK	OA	X Clock. Output clock at 56.448 MHz (PLL disabled) or 63.5045 (PLL enabled), which runs during MDP Normal Mode and is turned off during Sleep Mode.
YCLK	OA	Y Clock. Output clock at 28.224 MHz, which runs during MDP Normal Mode and is turned off during Sleep Mode.
SYCLK	OA	System Clock. Output clock at 28.224 MHz, which runs during MDP Normal Mode and during Sleep Mode.
PLLVDD	PLL	PLLVDD Connection. For the 144-pin TQFP, connect to +3.3V (VDD) through 10 Ω and to AGND through 10 (+) μ F. For the 100-pin PQFP, connect to +3.3V (VDD) through 10 Ω and to DGND through 10 (+) μ F.
PLLGNDD	PLL	PLLGNDD Connection. For the 144-pin TQFP, connect to AGND. For the 100-pin PQFP, connect to DGND.
PARALLEL HOST INTERFACE		
Address, data, control, and interrupt hardware interface signals allow MDP connection to an 8086-compatible microprocessor bus. With the addition of external logic, the interface can be made compatible with a wide variety of other microprocessors such as the 6502, 8086 or 68000. The microprocessor interface allows a microprocessor to change MDP configuration, read or write channel and diagnostic data, and supervise MDP operation by writing control bits and reading status bits.		
D0–D7	IA/OB	Data Lines. Eight bidirectional data lines (D0–D7) provide parallel transfer of data between the host and the MDP. The most significant bit is D7. Data direction is controlled by the Read Enable and Write Enable signals.
RS0–RS4	IA	Register Select Lines. The five active high register select lines (RS0–RS4) address interface memory registers within the MDP interface memory. These lines are typically connected to the five least significant lines (A0–A4) of the address bus. The MDP decodes RS0 through RS4 to address one of 32 internal interface memory registers (00–1F). The most significant address bit is RS4, while the least significant address bit is RS0. The selected register can be read from or written into via the 8-bit parallel data bus (D0–D7). The most significant data bit is D7, while the least significant data bit is D0.
~CS	IA	Chip Select. ~CS selects the MDP for microprocessor bus operation. ~CS is typically generated by decoding host address bus lines.
~READ	IA	Read Enable. During a read cycle (~READ asserted), data from the selected interface memory register is gated onto the data bus by means of three-state drivers in the MDP. These drivers force the data lines high for a one bit, or low for a zero bit. When not being read, the three-state drivers assume their high-impedance (off) state.
~WRITE	IA	Write Enable. During a write cycle (~WRITE asserted), data from the data bus is copied into the selected MDP interface memory register, with high and low bus levels representing one and zero bit states, respectively.
IRQ	OA	Interrupt Request. The MDP IRQ output may be connected to the host processor interrupt request input in order to interrupt host program execution for immediate MDP service. The IRQ output can be enabled in the MDP interface memory to indicate immediate change of conditions. The use of IRQ is optional depending upon MDP application. The IRQ output is driven by a TTL-compatible CMOS driver.
VOICE SERIAL INTERFACE (144-PIN R6789)		
Timing and data signals provide a voice serial interface which is used to transfer 16-bit linear or 8-bit A-Law/ μ -Law PCM voice samples in full-duplex speakerphone form with acoustic echo cancellation to and from the host. These signals can be used in concurrent voice and data applications by the host.		
SR8OUT	OA	Serial Data Out. Analog voice on the MICV input pin is converted to 16-bit linear or 8-bit A-Law/ μ -Law PCM digital voice samples and output on this pin in serial form to the host.
SR8IN	IN	Serial Data In. Digital voice in 16-bit linear or 8-bit A-Law/ μ -Law PCM form is received from the host on this serial data input pin, converted to analog form and routed to the SPKR output pin.
SR4CLK	IA	Serial Shift Clock. Serial bit clock used to shift data bits into the MDP on the SR8IN pin and out of the MDP on the SR8OUT pin. Connect to MDP CLKOUT (PB0) pin.
SA4CLK	IA	Sample Shift Clock. Serial frame clock used to synchronize words shifted in on the SR8IN pin and shifted out on the SR8OUT pin. SA4CLK clock edges must align with the rising edge of SR4CLK.

Table 2-3. MDP Signal Definitions (Cont'd)

Label	I/O Type	Signal Name/Description
DTE SERIAL INTERFACE		
Timing, data, control, and status signals provide a V.24-compatible serial interface. These signals are TTL compatible in order to drive the short wire lengths and circuits normally found within a printed circuit board, stand-alone modem enclosures, or equipment cabinets. For driving longer cables, these signals can be easily converted to EIA/RS-232-D voltage levels.		
TXD	IA	Transmitted Data. The MDP obtains serial data to be transmitted from the local DTE on the Transmitted Data (TXD) input.
RXD	OA	Received Data. The MDP presents received serial data to the local DTE on the Received Data (RXD) output.
~RTS	IA	Request to Send. Activating ~RTS causes the MDP to transmit data on TXD when ~CTS becomes active. The ~RTS pin is logically ORed with the RTS bit. ~RTS is also used to initiate the training sequence in half-duplex modes.
~CTS	OA	Clear To Send. ~CTS active indicates to the local DTE that the MDP will transmit any data present on TXD. CTS response times from an active condition of RTS are shown in Table 1-3.
~RLSD	OA	Received Line Signal Detector. ~RLSD active indicates to the local DTE that energy above the receive level threshold is present on the receiver input, and that the energy is not a training sequence. One of four ~RLSD receive level threshold options can be selected (RTH bits). A minimum hysteresis action of 2 dB exists between the actual off-to-on and on-to-off transition levels. The threshold level and hysteresis action are measured with a modulated signal applied to the Receiver Analog (RXA) input. Note that performance may be degraded when the received signal level is less than -43 dBm. The ~RLSD on and off thresholds are host programmable in DSP RAM.
~DTR	IA	Data Terminal Ready. In V.8, V.90, K56flex, V.34, V.32 bis, V.32, V.22 bis, V.22, or Bell 212A configuration, activating ~DTR initiates the handshake sequence. The DATA bit must be set to complete the handshake. In V.21, V.23, or Bell 103 configuration, activating ~DTR causes the MDP to enter the data state provided that the DATA bit is a 1. If in answer mode, the MDP immediately sends answer tone. In these modes, if controlled carrier is enabled, carrier is controlled by RTS. During the data mode, deactivating ~DTR causes the transmitter and receiver to turn off and return to the idle state. The ~DTR input and the DTR control bit are logically ORed.
~DSR	OA	Data Set Ready. ~DSR ON indicates that the MDP is in the data transfer state. ~DSR OFF indicates that the DTE is to disregard all signals appearing on the interchange circuits except Ring Indicator (~RI). ~DSR is OFF when the MDP is in a test mode (i.e., local analog or remote digital loopback). The DSR status bit reflects the state of the ~DSR output.
~RI	OA	Ring Indicator. ~RI output follows the ringing signal present on the line with a low level (0 V) during the ON time, and a high level (+3.3V) during the OFF time coincident with the ringing signal. The RI status bit reflects the state of the ~RI output.
TDCLK	OA	Transmit Data Clock. The MDP outputs a synchronous Transmit Data Clock (TDCLK) for USRT timing. The TDCLK frequency is the data rate ($\pm 0.01\%$) with a duty cycle of $50 \pm 1\%$. The TDCLK source can be internal, external (input on XTCLK), or slave (to ~RDCLK) as selected by TXCLK bits in interface memory.
XTCLK	IA	External Transmit Clock. In synchronous communication, an external transmit data clock can be connected to the MDP XTCLK input. The clock supplied at XTCLK must exhibit the same characteristics as TDCLK. The XTCLK input is then reflected at the TDCLK output.
~RDCLK	OA	Receive Data Clock. The MDP outputs a synchronous Receive Data Clock (~RDCLK) for USRT timing. The ~RDCLK frequency is the data rate ($\pm 0.01\%$) with a duty cycle of $50 \pm 1\%$. The ~RDCLK low-to-high transitions coincide with the center of the received data bits.

Table 2-3. MDP Signal Definitions (Cont'd)

Label	I/O Type	Signal Name/Description
TELEPHONE LINE/TELEPHONE/AUDIO INTERFACE SIGNALS AND REFERENCE VOLTAGE		
TXA1, TXA2	O(DF)	Transmit Analog 1 and 2 Output. The TXA1 and TXA2 outputs are differential outputs 180 degrees out of phase with each other. Each output can drive a 300 Ω load. Typically, TXA1 and TXA2 are connected to the telephone line interface or an optional external hybrid circuit.
RIN	I(DA)	Receive Analog Input. RIN is a single-ended input with 70K Ω input impedance. Typically, RIN is connected to telephone line interface or an optional external hybrid circuit. NOTE: If not used, do not tie directly to ground; this input has a bias voltage of +1.35V (VAA = +3.3V) or +2.5V (VAA = +5V).
RINGD	IA	Ring Detect. The RINGD input is monitored for pulses in the range of 15 Hz to 68 Hz. The frequency detection range may be changed by the host in DSP RAM. The circuit driving RINGD should be a 4N35 optoisolator or equivalent. The circuit driving RINGD should not respond to momentary bursts of ringing less than 125 ms in duration, or less than 40 VRMS (15 Hz to 68 Hz) across TIP and RING. Detected ring signals are reflected on the ~RI output signal as well as the RI bit.
~RLYA (~OHRC, ~CALLID)	OD	Relay A Control. The ~RLYA open drain output can directly drive a reed relay coil with a minimum resistance of 360 ohms (9.2 mA max. @ +3.3V). A clamp diode, such as a 1N4148, should be installed across the relay coil. An external transistor can be used to drive heavier loads (e.g., electro-mechanical relays). ~RLYA is controlled by host setting/resetting of the RA bit. In a typical application, ~RLYA is connected to the normally open Off-Hook relay (~OHRC). In this case, ~RLYA active closes the relay to connect the MDP to the telephone line. Alternatively, in a typical application, ~RLYA is connected to the normally open Caller ID relay (~CALLID). When the MDP detects a Calling Number Delivery (CND) message, the ~RLYA output is asserted to close the Caller ID relay in order to AC couple the CND information to the MDP RIN input (without closing the off-hook relay and allowing loop current flow which would indicate an off-hook condition).
~RLYB (~TALK)	OD	Relay B Control. The ~RLYB open drain output can directly drive a reed relay coil with a minimum resistance of 360 ohms (9.2 mA max. @ 3.3V). A clamp diode, such as a 1N4148, should be installed across the relay coil. An external transistor can be used to drive heavier loads (e.g., electro-mechanical relays). ~RLYB is controlled by host setting/resetting of the RB bit. In a typical application, ~RLYB is connected to the normally closed Talk/Data relay (~TALK). In this case, ~RLYB active opens the relay to disconnect the handset from the telephone line.
MICM	I(DA)	Modem Microphone Input. MICM is a single-ended microphone input. The input impedance is > 70k Ω . NOTE: If not used, do not tie directly to ground; this input has a bias voltage of +1.35V (VAA = +3.3V) or +2.5V (VAA = +5V).
SPK	O(DF)	Speaker Analog Output. The SPK analog output can originate from one of five different sources: RIN, TELIN, MICM or MICV or from the MDP's internal voice playback mode. The SPK on/off and three levels of attenuation are controlled by bits in DSP RAM. When the speaker is turned off, the SPK output is clamped to the voltage at the VC pin. The SPK output can drive an impedance as low as 300 ohms. In a typical application, the SPK output is an input to an external LM386 audio power amplifier.
SPKMD	OA	Modem Speaker Digital Output. The SPKMD digital output reflects the received analog input signal digitized to TTL high or low level by an internal comparator to create a PC Card (PCMCIA)-compatible signal.
VREF	REF	High Voltage Reference. Connect to VC through 10 μ F (polarized, + terminal to VREF) and 0.1 μ F (ceramic) in parallel.
VC	REF	Low Voltage Reference. For the 144-pin TQFP, connect to AGND through 10 μ F (polarized, + terminal to VC) and 0.1 μ F (ceramic) in parallel. For the 100-pin PQFP, connect to a ferrite bead and connect the other end of the ferrite bead to DGND through 10 μ F (polarized, + terminal to VC) and 0.1 μ F (ceramic) in parallel.
MICV	I(DA)	Voice Microphone Input. MICV is a single-ended microphone input. Typically, MICV is connected to a microphone output for recording voice e.g., in a speakerphone application. NOTE: If not used, do not tie directly to ground; this input has a bias voltage of +1.35V (VAA = +3.3V) or +2.5V (VAA = +5V).
TELIN	I(DA)	Telephone Analog Input. TELIN is a single-ended input with 70K Ω input impedance. Typically, TELIN is connected to a telephone handset microphone circuit. NOTE: If not used, do not tie directly to ground; this input has a bias voltage of +1.35V (VAA = +3.3V) or +2.5V (VAA = +5V).
TELOUT	O(DF)	Telephone Analog Output. TELOUT is a single-ended output that can drive a 300 Ω load. Typically, TELOUT is connected to a telephone handset speaker circuit.
MICBIAS	REF	Microphone Bias. Microphone bias reference voltage.

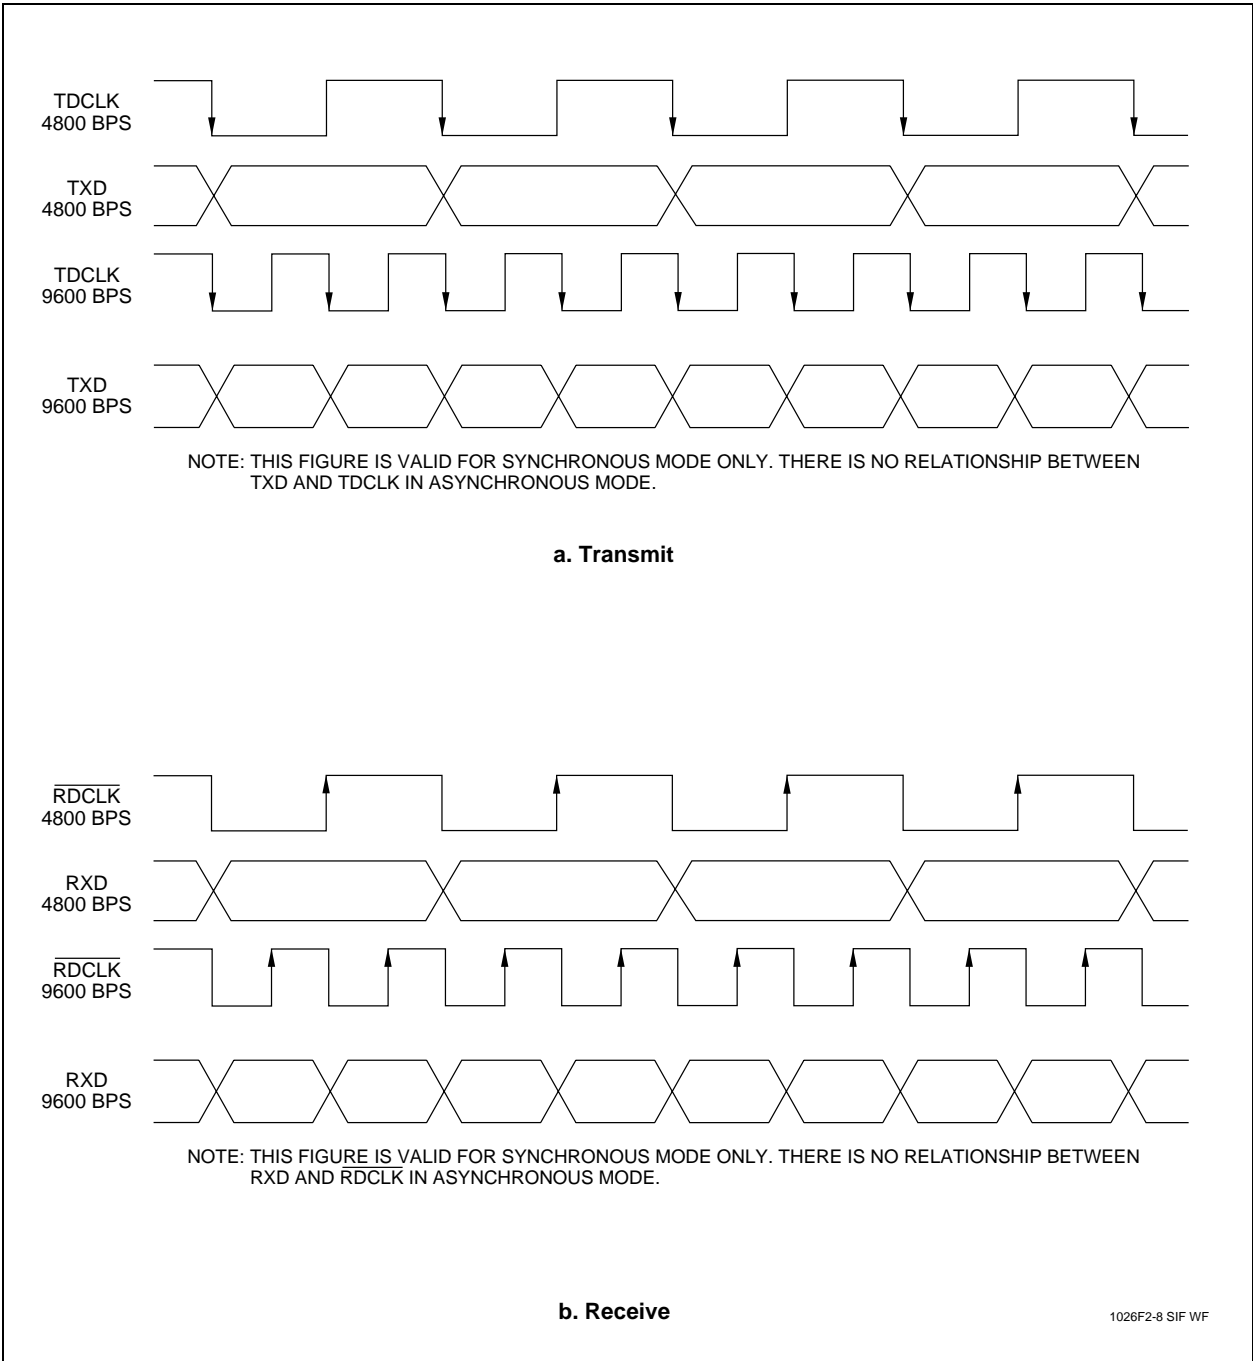

Figure 2-7. DTE Serial Interface Waveforms

2.2 LINE TRANSFORMER REQUIREMENTS FOR K56flex, V.34/V.32

K56flex/V.34/V.32 bis/V.32 places high requirements upon the Data Access Arrangement (DAA) to the telephone line. Any non-linear distortion generated by the DAA in the transmit direction cannot be canceled by the MDP's echo canceller and interferes with data reception. The designer must, therefore, ensure that the total harmonic distortion seen at the RXA input to the MDP be at least 45 dB (RC336) or 65 dB (RCDL56) below the minimum level of received signal. Due to the wider bandwidth requirements in K56flex and V.34, the DAA must maintain linearity from 10 Hz to 3954 Hz (RC336) or 4000 Hz (RCDL56).

Note that the major source of non-linear distortion in a DAA is the line transformer. A suitable line transformer is the MIDCOM 671-8262 or equivalent.

When designing a DAA, the designer should take into account a worst case subscriber line, giving very poor matching to the DAA hybrid circuit and resulting in a large near-end echo.

3. SOFTWARE INTERFACE

MDP functions are implemented in DSP firmware (code).

3.1 INTERFACE MEMORY

The MDP DSP communicates with the host processor by means of a dual-port, interface memory. The interface memory contains thirty-two 8-bit registers, labeled register 00 through 1F. Each register can be read from, or written into, by both the host and the DSP. The host communicates with the DSP interface memory via the microprocessor bus.

The host can control MDP operation by writing control bits to DSP interface memory and writing parameter values to DSP RAM through the interface memory. The host can monitor MDP operation by reading status bits from DSP interface memory and reading parameter values from DSP RAM through interface memory.

3.1.1 Interface Memory Map

An interface memory map of the 32 addressable registers in the MDP is shown in Figure 3-1. These 8-bit registers may be read or written during any host read or write cycle. In order to operate on a single bit or a group of bits in a register, the host processor must read a register then mask out unwanted data. When writing a single bit or group of bits in a register, the host processor must perform a read-modify-write operation. That is, read the entire register, set or reset the necessary bits without altering the other register bits, then write the unaffected and modified bits back into the interface memory.

3.1.2 Interface Memory Signal Definitions

The individual bits in the interface memory are defined in Table 3-1. The bits in the interface memory are referred to using the format Z:Q. The register number is specified by Z (00 through 1F) and the bit number by Q (0 through 7, 0 = LSB).

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Register (Hex)	Bit

Notes:								
1. — in the “Bit” columns indicates reserved for MDP use only.								

Figure 3-1. MDP Interface Memory Map

Table 3-1. MDP Interface Memory Bit Definitions

Mnemonic	Location	Default	Name/Description
AADET	0Ch:7	–	AA Detector. When set, status bit AADET indicates that a V.32 bis/V.32 AA sequence has been detected. This bit is reset by the MDP at the start of the CC sequence. This bit is not valid during rate renegotiation. (V.32 bis, V.32)
ABCODE	14h:0–7	00	Abort Code. If the handshake fails, an abort code is written into ABCODE. This code indicates the point in the handshake where the failure occurred. The abort code is not cleared by the MDP but may be cleared by the host after it has been read. The abort codes and their meanings are listed in Table 3-2. Refer to ITU-T recommendations for meanings of the signal mnemonics used. (V.8, V.90, K56flex, V.34, V.32 bis, V.32) The ABCODE register is also used for RAM code download procedures (see Section 16 for details).
ACDET	0Ch:6	–	AC Detector. When set, status bit ACDET indicates that a V.32 bis/V.32 AC sequence has been detected. This bit is reset by the MDP when a CA sequence or an energy dropout is detected. This bit is not valid during rate renegotiation. Active when DTR = 1 and DATA = X or when DTR = 0 and DATA = 0. (V.32 bis, V.32)
ASYN	08h:7	0	Asynchronous/Synchronous. When configuration bit ASYN is set, asynchronous mode is selected; when 0, synchronous mode is selected. When the ASYN bit changes from a 0 to a 1, the asynchronous to synchronous converter is configured according to the EXOS, PEN, STB and WDSZ bits at that time (EXOS, PEN, STB and WDSZ must be configured before ASYN changes from a 0 to a 1.) ASYN may be used to switch between synchronous and asynchronous modes only when RTS is OFF and TDBE = 1 in idle or data mode. Do not set this bit in V.21, V.23, or Bell 103 serial mode. Set this bit in V.21, V.23, or Bell 103 parallel mode. Note that the HDLC bit must be reset to 0 when ASYN is a 1. (V.90, K56flex, V.34, V.32 bis, V.32, V.22 bis, V.22, Bell 212A)
ATBEL	0Bh:3	–	Bell Answer Tone Detector. When set, status bit ATBEL signifies that the MDP receiver detected a 2225 Hz answer tone. The bit is set when the answer tone is detected, and is reset when the tone ends. ATBEL is active only when the DATA bit is reset and the MDP is in originate mode. [Bell 212A, Bell 103, tone modes (CONF = 80h, 81h, or 83h)]
ATV25	0Bh:4	–	V25 Answer Tone Detector. When set, status bit ATV25 signifies that the MDP receiver detected a 2100 Hz answer tone. The bit is set when the answer tone is detected, and is reset when the tone ends. ATV25 is active only when the DATA bit is reset before energy is present at RXA and the MDP is in originate mode. [V.90, K56flex, V.8, V.32 bis, V.32, V.22 bis, V.22, V.23, V.21, tone modes (CONF = 80h, 81h, or 83h)]
AUTO	15h:3	0	Automatic Mode Change Enable. When control bit AUTO is set, the MDP will automatically determine the communication standard of the remote modem and configure itself accordingly. The automode algorithm is based on the EIA/TIA PN-2330 specification. The possible operating modes are: V.32 bis/V.32, V.22 bis, V.22, Bell 212A, Bell 103, V.23 and V.21. Note that TONEB is not available for use by the host when automode function is used in answer mode To operate in automode, the MDP must be configured to V.8, V.32, or V.32 bis in CONF, the AUTO bit must be set, and the DATA bit reset. Setting DTR or activating the DTR pin will then commence the handshake. The AUTO bit will be reset and the DATA bit will be set when the MDP has determined the remote modem type. CONF will then contain the configuration code of the modem type found. It is recommended that the AUTO bit remain reset until answer tone has been detected when in originate mode. The automode function will select V.23 mode only if the remote modem is configured for 1200 receive originate or 75 receive answer. (V.90, K56flex, V.8, V.32 bis, V.32)

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
BRKD	0Eh:6	–	Break Detected. When set, status bit BRKD indicates the MDP is receiving continuous space in a synchronous mode. When reset, continuous space is not being received.
BRKS	11h:7	0	Break Sequence. When control bit BRKS is set in parallel asynchronous mode, the MDP will send continuous space. When BRKS is reset, the MDP will transmit parallel data from the TBUFFER. (This bit is valid only when TPDM = 1.)
CADET	0Ch:5	–	CA Detector. When set, status bit CADET indicates that a CA sequence has been detected. This bit is reset by the MDP when a AC sequence is detected. This bit is not valid during rate renegotiation. (V.32 bis, V.32)
CC	09h:6	0	Controlled Carrier. When control bit CC is set and the LL bit is set, the MDP operates in controlled carrier; when bit CC is reset, the MDP operates in constant carrier. Controlled carrier allows the MDP transmitter to be controlled by the RTS pin or the RTS bit (Table 1-3). When the RTS pin is asserted, or the RTS bit set, the transmitter immediately sends scrambled ones for 270 ms and then turns on the ~CTS signal and the CTS bit. (V.22 bis, V.22, V.23, V.21, Bell 212A). (See LL bit description.) In V.34 fax mode, control bit CC is used to indicate the desired receive control channel date rate (1 = 2400 bps, 0 = 1200 bps). The actual rate used depends on the asymmetric bit settings in both modems. Bit 6 in 3DFh must be set to 1 in both modems to allow control channel asymmetric data rates.
CCMODE	0Ch:4	--	Control Channel Mode. In V.34 fax mode, when status bit CCMODE is set, the modem enters CC mode. This bit is not timed precisely. When the host turns off the RTS bit and ends the PC mode, it must wait until this bit is set and then, typically, an additional 5 ms before starting the transmission of CC data. (V34 Fax mode.)
CCRTN	06h:5	0	Control Channel Retrain. In V.34 fax mode, either the source or the recipient modem may initiate a control channel retrain by setting bit CCRTN. Bit CCRTN should only be set when the modem is in control channel mode. The modem will reset bit CCRTN when the retrain process is complete. The retrain process can be monitored by observing SECAXB and SECTXB.
CCDET	0Ch:4	–	CC Detector. When set, status bit CCDET indicates that a CC sequence has been detected. This bit is reset by the MDP when an energy dropout is detected. This bit is not valid during rate renegotiation. (V.32 bis, V.32)
CDEN	02h:4	0	Coder Enable. In receive voice mode (CONF bits = ACh, 80h, 81h, 83h, or 86h, and RXV = 1), control bit CDEN = 1 selects ADPCM receive mode. In this mode, the MDP performs ADPCM coding and places the coder output into the Voice Receive Buffer (VBUFR). CDEN = 0 selects receive pass-through mode (see RXV bit).
CEQ	05h:3	1	Compromise Equalizer Enable. When control bit CEQ is set, the transmitter's digital compromise equalizer is inserted into the transmit path. CEQ should be reset during local analog loopback and in FSK modes (except V.23/1200TX and V.8) to ensure uniform transmit levels for both mark and space frequencies.
CODBITS	02h:1-0	–	Coder No. of Bits. Defines the number of bits per sample (2, 3, or 4) used by the ADPCM coder. (ADPCM receive mode only.)

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
CONF	12h:0–7	76	Modem Configuration (Cont'd). NOTES: <ol style="list-style-type: none"> The MDP can transmit a GSTN Cleardown sequence during a retrain (V.32 bis/V.32) or a rate renegotiation (V.90, K56flex, V.34/V.32 bis/V.32). In V.32 bis/V.32, the remote modem will automatically detect the Cleardown sequence and both modems will drop carrier at the end of the retrain or rate renegotiation. In V.34, the MDP will indicate the Cleardown detection by writing a 96h in ABCODE. The host must terminate the connection by resetting DTR and setting NEWC (see Function 75 in Section 4). Configuration 82 allows for possible fall forward to 2400 bps. The MDP transmits one or two tones depending upon the selected mode. The tone frequencies and levels are host programmable in DSP RAM. Voice mode can run concurrently; see TXV and RXV bits.
CRCS	0Ah:2	0	CRC Sending. When set, status bit CRCS indicates that the transmitter is sending the CRC (2 bytes) in HDLC (SDLC) mode. A 0 indicates that the CRC is not being sent. Either a 16-bit (default) or 32-bit CRC may be sent as selected by the ITU-T CRC32 parameter in RAM (see Section 4.4, Function 52). To disable the CRC transmission in HDLC mode, set bit 0B3h: 6. This is needed for H.324 applications. (See Section 5.1).
CTS	0Fh:5	–	Clear To Send. When set, status bit CTS indicates to the DTE that the training sequence has been completed and any data present at TXD (serial mode) or in TBUFFER (parallel mode) will be transmitted (see TPDM). CTS response times from an RTS ON or OFF transition after the MDP has completed a handshake are shown in Table 1-3. The CTS OFF-to-ON response time is programmable in DSP RAM.
DATA	09h:2	1	Data. Control bit DATA is used to prevent the transmitter from entering and proceeding with the handshake (start-up) sequence and to ignore all V.24 interface signals. When control bit DATA is reset, the MDP is prevented from entering and proceeding with the handshake (start-up) sequence and will ignore all V.24 interface signals. This bit should be set by the host at a suitable time after completion of dialing or answering. Basic procedure for originating a call in V.8, V.32 bis/V.32 using DATA: Reset both DATA and DTR. Establish a call. Detect answer tone using ATV25. After receiving answer tone for 1 second, configure to the appropriate mode, set DTR and DATA. (If automode is to be used, set AUTO and leave DATA reset.) The handshake will now proceed. NOTE: If configured directly for V.32bis/V.32, set DATA no later than 20 ms after detecting ACDET = 1 for compatibility with V.32 modems which send the minimum allowable AC length of 53.3 ms.
DCDEN	02h:5	0	Decoder Enable. In transmit voice mode (CONF bits = ACh, 80h, 81h, 83h, or 86h and TXV = 1), control bit DCDEN = 1 selects ADPCM transmit voice mode. In this mode, the MDP performs ADPCM decoding on the contents of the Voice Transmit Buffer (VBUFT). DCDEN = 0 selects transmit voice pass-through mode (see TXV bit).
DECBITS	06h:1-0	–	Decoder No. of Bits. DECBITS defines the number of bits per sample (2, 3, or 4) used by the ADPCM decoder. (ADPCM transmit mode only.)

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description																																				
DISDET	0Bh:1	–	<p>Disconnect Detect. When set, status bit DISDET indicates that a line disconnection has occurred and the MDP has synchronized onto it's own transmit signal (i.e., EQM acceptable and RLSD still on). The host may then issue a retrain to confirm the disconnection and subsequently drop the line if a response is not detected. Bit DISDET will remain set until reset by the host. (V.32 bis, V.32) Do not check in other modes.</p> <p>Note: If RLSD turns off or EQM increases to an unacceptable value due to a disconnection, bit DISDET will not turn on.</p>																																				
DMAE	1Ah:4	0	<p>DMA Signals Enabled. When set to a 1, control bit DMAE converts the ~RI and ~DSR output lines to the TXRQ (Transmitter Request) and RXRQ (Receiver Request) output lines, respectively. TXRQ is a high active signal that follows the state of the TDBE bit and the RXRQ is a high active signal that follows the state of the RDBF bit. DMA is available in asynchronous, synchronous and HDLC modes. Bit FIFOEN must be set in asynchronous modes in order to obtain the RXRQ interrupt. (TPDM = 1)</p>																																				
DSR	0Fh:4	–	<p>Data Set Ready. Status bit DSR operation is in accordance with circuit 107 of the ITU-T specifications.</p>																																				
DTDET	1Bh:6	–	<p>Dual Tone Detected. When configured as a DTMF Receiver, the MDP sets status bit DTDET when a signal is received that satisfies all DTMF criteria except on-time, off-time, and cycle-time. The encoded DTMFW Output Word (1Bh:3-0) value is available when DTDET is set.</p>																																				
DTMF	09h:5	1	<p>DTMF Select. When the MDP is configured for dialing mode (CONF = 81h), the MDP will dial using DTMF tones or pulses. When control bit DTMF is set, the MDP will dial using DTMF tones. When DTMF is reset, the MDP will dial using pulses. The DTMF bit can be changed during the dialing process to allow either tone or pulse dialing of consecutive digits. When in dialing mode, the data placed in the Transmit Data Buffer is treated as digits to be dialed. The number to be dialed must be represented by two hexadecimal digits (e.g., if a 9 is to be dialed, then a 09 must be written to the Transmit Data Buffer). Also, see TDBE bit.</p> <p>Dialing timing and power levels are host programmable in DSP RAM (Table 4-1).</p> <p>Pulse dialing defaults to the ~OHRC output. The pulse dialing output is controlled by bit 0D4h:6 [0 = ~OHRC (~RLYA) output; 1 = ~TALK (~RLYB) output] when in dial mode. The output may be selected using RAM access method 1 (see Section 4).</p>																																				
DTMFD	1Bh:4	–	<p>DTMF Signal Detected. When configured as a DTMF receiver, the MDP sets status bit DTMFD when a DTMF signal has been detected that satisfies all specified DTMF detect criteria.</p>																																				
DTMFW	1Bh:3-0	–	<p>DTMF Output Word. When the MDP is configured as a DTMF receiver and status bit DTDET is set by the MDP, the encoded DTMF output is written into DTMFW.</p> <table border="1"> <thead> <tr> <th>DTMF Symbol</th><th>Encoded Output (Hex)</th><th>DTMF Symbol</th><th>Encoded Output (Hex)</th></tr> </thead> <tbody> <tr> <td>0</td><td>0</td><td>8</td><td>8</td></tr> <tr> <td>1</td><td>1</td><td>9</td><td>9</td></tr> <tr> <td>2</td><td>2</td><td>*</td><td>A</td></tr> <tr> <td>3</td><td>3</td><td>#</td><td>B</td></tr> <tr> <td>4</td><td>4</td><td>A</td><td>C</td></tr> <tr> <td>5</td><td>5</td><td>B</td><td>D</td></tr> <tr> <td>6</td><td>6</td><td>C</td><td>E</td></tr> <tr> <td>7</td><td>7</td><td>D</td><td>F</td></tr> </tbody> </table> <p>The host should wait until the DTMFD bit is set before reading the DTMFW bit.</p>	DTMF Symbol	Encoded Output (Hex)	DTMF Symbol	Encoded Output (Hex)	0	0	8	8	1	1	9	9	2	2	*	A	3	3	#	B	4	4	A	C	5	5	B	D	6	6	C	E	7	7	D	F

7	7	D	F																																				

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
DTR	09h:0	0	<p>Data Terminal Ready. In V.90, K56flex, V.8, V.34, V.32 bis/V.32, V.22/V.22 bis, and Bell 212A modes, setting control bit DTR initiates a handshake sequence. If in answer mode, the MDP will immediately send answer tone.</p> <p>In V.21, V.23, and Bell 103 modes, DTR must be set for the MDP to enter data state providing DATA bit is set. If in answer mode, the MDP will send answer tone. In these configurations, if controlled carrier is selected, the carrier is controlled by the RTS pin or RTS bit.</p> <p>During the data mode, resetting DTR will cause the transmitter to turn off.</p> <p>The DTR bit parallels the operation of the hardware ~DTR control input. These inputs are ORed by the MDP.</p>
EARC	15h:0	0	<p>Extended Automatic Rate Change. Control bit EARC is used to enable automatic rate adaption or automatic rate change during the handshake. When EARC is set, do not change the contents of CONF when performing a rate change. This bit is typically used for handshake and retrain only. Turn off EARC once connected. Re-enable EARC if initiating or detecting a retrain. This bit is not advisable for rate negotiation. (See Section 4 for detailed information about auto rate adaption.) (K56flex, V.34, V.32 bis, V.32).</p>
EDET	1Bh:7	–	<p>DTMF Early Detection. When configured as a DTMF receiver, the MDP sets status bit EDET to indicate that the received signal is probably a DTMF signal.</p>
EPT	03h:7	0	<p>Echo Protector Tone Enable. When control bit EPT is set, an unmodulated carrier is transmitted for 185 ms (SEPT = 0) or 30 ms (SEPT = 1) followed by 20 ms of no transmitted energy prior to the transmission of the training sequence. When EPT is reset, neither the echo protector tone nor the 20 ms of no energy are transmitted prior to the transmission of the training sequence. (V.33, V.17, V.29, V.27)</p> <p>The echo protector tone is typically used in V.27 ter and V.29 over dial-up lines. The tone is sent prior to the training sequence to ensure that the echo suppressors are pointing in the correct direction.</p>
EQMAT	0Bh:0	0	<p>EQM Above Threshold. Status bit EQMAT indicates that the measured EQM is above (1) or not above (0) the threshold value programmed in DSP RAM. The default threshold is 3000h. This bit must be cleared by the host. (See Section 4, Function 46.)</p>
EXL3	15h:1	0	<p>External Loop 3 Selector. When control bits L3ACT and EXL3 are both set, the signal path for local analog loopback is external to the MDP. When L3ACT is set but EXL3 is reset, the local analog loop signal path is internal to the MDP. This bit is used for measuring the transmit spectrum in V.34, V.32 and V.22 bis modes, without having to connect to a remote modem.</p> <p>V.22 bis/V.22 modes send the low carrier by default. To send the high carrier, write 5555h to location B42h after setting DTR.</p> <p>To send space frequency in FSK modes, use ASYN = 1, TPDM = 1, RTS = 1, and BRKS = 1. BRKS = 0 will cause mark to be sent.</p> <p>(See L3ACT.)</p>
EXOS	06h:6	0	<p>Extended Overspeed. When control bit EXOS is set, Extended Overspeed mode is selected in the async-to-sync converter and in the sync-to-async converter. This bit must be configured appropriately before the ASYN bit changes from a 0 to a 1 for asynchronous mode. (V.90, K56flex, V.34, V.32 bis, V.32, V.22 bis, V.22, Bell 212A)</p>

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
FE	0Ah:4	0	Framing Error. When set, status bit FE indicates that more than 1 in 8 (or 1 in 4 for extended overspeed) characters were received without a Stop bit in asynchronous mode or an ABORT sequence was detected in SDLC/HDLC synchronous mode. When reset, no framing error is detected. In voice receive mode, FE = 1 and PE = 1 denote the first low byte.
FED	0Fh:6	–	Fast Energy Detector. When status bit FED is set, energy in the passband above the selected receiver threshold has been detected (see RTH). DTR must be on in order for FED to function in full duplex modes (DATA = 1).
FIFOEN	04h:4	0	FIFO Enable. When control bit FIFOEN = 1, the host can input up to 16 bytes of data through TBUFFER, or voice samples through VBUFT, using the TDBE bit as a software interrupt or the TXRQ signal (DMAE = 1) as a DMA request interrupt. In HDLC, by default, if the host underruns the Transmit FIFO, the MDP will append a CRC. If bit 3A5h: 6 is set, the MDP will instead abort the frame and provide an abort code of 41h in ABCODE. The Receive FIFO is always enabled. The host may wait up to 16 byte-times before reading the data in RBUFFER. The RDBF bit or RXRQ signal (DMAE = 1) signals the availability of receive data to the host. The trigger level for RDBF bit/RXRQ signal is host programmable in DSP RAM. (See Section 4 for a detailed description about FIFO operation.) (TPDM = 1)
FLAGDT	0Ah:6	–	V.21 Channel 2 Flag Detected. When set, status bit FLAGDT indicates that V.21 Channel 2 Flags (7Eh) are being detected. (V.33, V.17, V.29, V.27 ter)
FLAGS	0Ah:1	0	Flag Sequence. When set, status bit FLAGS indicates that the transmitter is sending the Flag sequence in SDLC/HDLC mode, or a constant mark in parallel asynchronous mode. When reset, FLAGS indicates that the transmitter is sending data.
GTE	03h:1	0	Guard Tone Enable. When set, control bit GTE causes the specified guard tone to be transmitted (by the answering modem only) according to the state of the GTS bit. (V.22 bis, V.22)
GTS	03h:0	0	Guard Tone Select. When set, control bit GTS selects the 550 Hz tone; when reset, GTE selects the 1800 Hz tone. The selected guard tone will be transmitted only when GTE is enabled. The host must set NEWC after changing the GTS bit. (V.22 bis, V.22)
HDLC	06h:4	0	HDLC Select. When control bit HDLC is set, HDLC operation is enabled. When HDLC is reset, HDLC operation is disabled. The ASYN bit must be 0 and the TDBE bit must be 1 prior to setting HDLC to a 1. The HDLC bit is valid only in synchronous parallel data mode (ASYN = 0 and TPDM = 1). Not valid in FSK modes except V.21 channel 2. RTS must be off before switching in or out of HDLC mode while in DATA mode. Note that CRC generation can be disabled by setting bit 6 of RAM location 0B3h (default = CRC generation enabled).
HWRWK	15h:4	1	Host Write Wake up. When control bit HWRWK is set and the MDP is in sleep mode, a host write to any register with the exception of 1Dh:7-0, will bring the MDP out of sleep mode. (See SLEEP bit.)

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
L2ACT	07h:5	0	Loop 2 Activate. When control bit L2ACT is set, the receiver's digital output is connected to the transmitter's digital input (locally activated remote digital loopback) in accordance with V.54. A V.34 connection must be symmetrical in order to perform Loop 2. (Not valid in V.90, K56flex, or FSK modes.)
L3ACT	07h:3	0	Loop 3 Activate. When control bit L3ACT is set, the transmitter's analog output is coupled internally to the receiver's analog input through an attenuator (local analog loopback) in accordance with ITU-T Recommendation V.54. Optionally, the signal path for loop 3 can also be established externally to the MDP (see EXL3). The MDP may only be placed into loop 3 mode when in idle mode (~DTR signal is OFF and the DTR bit is reset). NEWC must be set after any change in the L3ACT bit. The loopback is then completed (terminated) by asserting ~DTR signal ON (low) or setting the DTR bit. The transmitter's compromise equalizer should be disabled, by resetting CEQ, during local analog loopback. (Not valid in V.90 or K56flex mode.)
LL	09h:3	0	Leased Line. When control bit LL is set, the MDP is in leased line operation; when 0, the MDP is in switched line operation, except as described below. For V.22 bis/V.22, set the LL bit and reset the CC bit. The MDP immediately sends scrambled ones and goes into data mode. A retrain may be required after the initial connection. (V.22 bis, V.22) For V.34, set the LL bit (V.8 should not be used in V.34 leased line). When DTR and DATA bits are set, the MDP continuously sends INFO0 until the remote modem is detected. (V.34) For V.32 bis/V.32, do not set LL bit. When DTR and DATA bits are set, the MDP continuously sends its preamble signal until the remote modem is detected. If desired, set the NV25 bit to prevent answer tone from being sent in answer mode. Note: Long term connection may require a retrain every 1-2 days in V.34 and V.32 bis modes in order to maintain connection stability. A rise in EQM will indicate the need for a retrain. Long term connections are not guaranteed to be error free. (Applicable to V.34, V.32 bis/V.32, and V.22 bis/V.22 only.)
MEACC	1Dh:7	0	Memory Access Enable. When control bit MEACC is set, the DSP accesses the RAM associated with the address in MEADDH and MEADDL. The MEMW bit determines if a read or write is performed. The DSP resets the MEACC upon RAM access completion.
MEADDL	1Ch:7-0	00	Memory Access Address Low (Bits 7-0). MEADDL contains the lower 8 bits (bits 7-0) of the address used to access MDP RAM via the memory access data LSB (18h) and MSB (19h) registers. (See Table 4-1.)
MEADDH	1Dh:3-0	0	Memory Access Address High (Bits 11-8). MEADDH contains the upper 4 bits (bits 11-8) of the address used to access MDP RAM via the memory access data LSB (18h) and MSB (19h) registers. (See Table 4-1.)
MEADDHB12	1Dh:6	0	Memory Access Address High Bit 12. MEADDHB12 contains bit 12 of the address used to access DDP RAM via the memory access data LSB (18h) and MSB (19h) registers. (See Table 4-1.)
MEDAL	18h:7-0	00	Memory Data LSB. MEDAL is the least significant byte (bits 7-0) of the 16-bit data word used in reading or writing data locations in MDP RAM.
MEDAM	19h:7-0	00	Memory Data MSB. MEDAM is the most significant byte (bits 15-8) of the 16-bit data word used in reading or writing data locations in MDP RAM.

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
MEMCR	1Dh:4	0	Memory Continuous Read. When set to a 1, control bit MEMCR instructs the DSP to automatically update the data in MEDAM and MEDAL based on the RAM address in MEADDH and MEADDL. without the host having to set the MEACC bit. The MDP will set the NEWS bit to a 1 when new data is available.
MEMW	1Dh:5	0	Memory Write. When MEMW is set and MEACC is set, the DSP copies data from the interface memory data registers MEDAL (18h) and MEDAM (19h) into the memory location addressed by MEADDL and MEADDH. When control bit MEMW is reset and MEACC is set, the DSP reads memory at the location addressed by MEADDL and MEADDH. The read data is stored into interface memory data registers MEDAL (18h) and MEDAM (19h).
MHLD	07h:0	0	Mark Hold. When control bit MHLD is set, the transmitter's digital input data is clamped to a mark. When MHLD is reset, the transmitter's input is taken from TXD or TBUFFER (see TPDM).
NCIA	1Fh:6	–	NEWC Interrupt Active. When the new configuration chip 0 interrupt is enabled (NCIE is set) and a new configuration is implemented (NEWC is reset), the MDP asserts IRQ and sets status bit NCIA to indicate that NEWC being reset caused the interrupt. NCIA and the interrupt request due to NEWC are cleared by the host writing a 0 into NCIE. (See NEWC and NCIE.)
NCIE	1Fh:2	0	NEWC Interrupt Enable. When control bit NCIE is set (interrupt enabled), the MDP will assert IRQ and set NCIA when the NEWC bit is reset by the MDP. When NCIE is reset (interrupt disabled), NEWC has no effect on IRQ or NCIA. (See NEWC and NCIA.)
NEWC	1Fh:0	0	New Configuration. Control bit NEWC must be set by the host after the host changes the configuration code in CONF (12h) or changes any of the following controls bits: CEQ (05h:3), DTMF (09h:5), GTE (03h:1), GTS (03h:0), L3ACT (07h:3), LL (09h:3), ORG(09h:4), RTH (13h:2,3), RXV (11h:3), SFRES (1Ah:7), SLEEP (15h:7), TLVL (13h:7-4), TXCLK (13h:1-0), TXV (11h:4), V21S (08h:5), or V23HDX (11h:2). This informs the MDP to implement the new configuration. The MDP resets the NEWC bit when the configuration change is implemented. A configuration change can also cause IRQ to be asserted. NOTE: NEWC should not be set once a connection is being attempted or completed. (See NCIE and NCIA.)
NEWS	1Fh:3	–	New Status. When set, status bit NEWS indicates that one or more status bits located in registers 0A–0F, 01, 12, 14, 16-17, 1A, or 1B have changed state (default = interrupt OFF), or a DSP RAM read or write has been completed (default = interrupt ON). This bit can be reset only by the host. The host may mask the effect of individual status bits upon NEWS by writing a mask value to DSP RAM (see Function 17 in Section 4). When set, this bit can cause IRQ to be asserted. (See NSIE and NSIA.) NOTE: When read/modifying register 1F, set NEWS = 1 to ensure that the host does not reset NEWS after the MDP DSP has set NEWS during read/modify. If NEWS = 0, setting NEWS to a 1 will not be accepted by the DSP and NEWS will remain a 0.
NRZIEN	04h:2	0	NRZI Enable. When set, control bit NRZIEN enables NRZI transmitter encoding and receiver decoding in all synchronous and HDLC modes. When NRZIEN is reset, NRZ encoding and decoding is used.
NSIA	1Fh:7	–	NEWS Interrupt Active. When the new status interrupt is enabled (NSIE is set) and a change of status occurs (NEWS is set), the MDP asserts IRQ and sets status bit NSIA to indicate that NEWS being set caused the interrupt. NSIA and the interrupt request due to NEWS are cleared when the host writes a 0 to NEWS. (See NEWS and NSIE.)

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description															
NSIE	1Fh:4	0	NEWS Interrupt Enable. When control bit NSIE is set (interrupt enabled), the MDP will assert IRQ and set NSIA when NEWS is set by the MDP. When NSIE is reset (interrupt disabled), NEWS has no effect on IRQ or NSIA. (See NEWS and NSIA.)															
NV25	09h:7	0	No V.25 Answer Tone. When control bit NV25 is set, the MDP will not transmit the 2100 Hz ITU-T answer tone when a handshake sequence is initiated and the MDP is in answer mode. (V.32 bis, V.32, V.22 bis, V.22, V.23, V.21) (Not valid in AUTO mode.)															
OE	0Ah:3	0	Overrun Error. When set, status bit OE indicates that the Receiver Data Buffer (RBUFFER) was loaded from the RXA input before the host read the old data from RBUFFER. When reset, RBUFFER was read before new receive data was loaded into RBUFFER. This is valid for both ASYNC mode (ASYN = 1) and SDLC/HDLC mode. This bit must be reset by the host.															
ORG	09h:4	0	Originate. When configuration bit ORG is set, the MDP is in originate mode; when reset, the MDP is in answer mode. Since this is a configuration bit, the NEWC bit must be set after any change in the ORG bit. For K56flex, see ORG bit description in Section 14. For V.90, see ORG bit description in Section 15.															
OTS	1Bh:5	–	DTMF On-Time Satisfied. When configured as a DTMF receiver, the MDP sets status bit OTS after the on-time criteria is satisfied. This bit is reset by the MDP after DTMFD is set or if the received signal fails to satisfy the DTMF off-time criteria.															
P2DET	0Dh:7	0	P2 Sequence Detected. When status bit P2DET is set, the MDP is detecting the P2 portion of the training sequence. When P2DET is reset, P2 is not being detected. (V.33, V.17, V.29, V.27)															
PARSL	11h:6-5	00	Parity Select. Parity Select. Control bits PARSL select the method by which parity is generated and checked during the asynchronous parallel data mode (ASYN = 1). The options are: <table><tr><th>6</th><th>5</th><th>Parity Selected</th></tr><tr><td>0</td><td>0</td><td>Stuff Parity ("9th Data Bit") (see TXP, RXP)</td></tr><tr><td>0</td><td>1</td><td>Space Parity</td></tr><tr><td>1</td><td>0</td><td>Even Parity</td></tr><tr><td>1</td><td>1</td><td>Odd Parity</td></tr></table>	6	5	Parity Selected	0	0	Stuff Parity ("9th Data Bit") (see TXP, RXP)	0	1	Space Parity	1	0	Even Parity	1	1	Odd Parity
6	5	Parity Selected																
0	0	Stuff Parity ("9th Data Bit") (see TXP, RXP)																
0	1	Space Parity																
1	0	Even Parity																
1	1	Odd Parity																
PE	0Ah:5	0	Parity Error. When set, status bit PE indicates that a character with bad parity was received in the asynchronous mode, or bad CRC was detected in the SDLC/HDLC synchronous mode. When reset, a character with good parity was received. In voice receive mode, FE = 1 and PE = 1 denote the first low byte.															
PEN	06h:3	0	Parity Enable. When control bit PEN is set, parity is enabled in asynchronous mode. This bit must be configured appropriately before the ASYN bit changes from a 0 to a 1 for asynchronous mode. (V.90, K56flex, V.34, V.32 bis, V.32, V.22, V.22 bis, Bell 212A)															
PNDDET	0Dh:6	–	PN Sequence Detected. Status bit PNDDET indicates that the PN portion of the training sequence is being detected (set) or is not being detected (reset). (V.33, V.17, V.29, V.27 ter)															
PNSUC	0Ah:7	0	PN Success. When status bit PNSUC is set, the MDP has successfully trained at the end of the PN portion of the high speed training sequence. When PNSUC is reset, a successful training has not occurred. (V.33, V.17, V.29, V.27 ter)															
RA	07h:1	0	Relay A Activate. When control bit RA is set, the ~OHRC output (~RLYA) is active; when reset, the ~OHRC output is off (high).															
RB	04h:7	0	Relay B Activate. When control bit RB is set, the ~TALK output (~RLYB) is active; when reset, the ~TALK output is off (high).															

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
RBUFFER	00h:7-0	–	Receive Data Buffer. The host obtains channel data from the MDP receiver in the parallel data mode by reading a data byte from the RBUFFER. The RBUFFER contains the received data when the RDBF bit is set. (See RDBF, RDBIE, and RDBIA.)
RDBF	1Eh:0	–	Receive Data Buffer Full. When set, status bit RDBF signifies that the receiver wrote valid data into RBUFFER (00h). This condition can also cause IRQ to be asserted. The host reading RBUFFER resets the RDBF and RDBIA bits. RDBF will remain set until the Receiver FIFO is emptied. (See RDBIE and RDBIA.)
RDBIA	1Eh:6	–	Receive Data Buffer Interrupt Active. When the receive data buffer interrupt is enabled (RDBIE is set) and RBUFFER (00h) is written to by the MDP (RDBF is set), the MDP asserts IRQ and sets RDBIA to indicate that RDBF being set caused the interrupt. The host reading RBUFFER resets the RDBIA bit and clears the interrupt request due to RDBF. (See RDBF and RDBIE.)
RDBIE	1Eh:2	0	Receive Data Buffer Interrupt Enable. When control bit RDBIE is set (interrupt enabled), the MDP will assert IRQ and set the RDBIA bit when RDBF is set by the MDP. When RDBIE is reset (interrupt disabled), RDBF has no effect on IRQ or RDBIA. (See RDBF and RDBIA.)
RDL	07h:6	0	Remote Digital Loopback. When set, control bit RDL causes the MDP to initiate a V.22 bis request for the remote modem to go into digital loopback; RXD is clamped to a mark and the CTS bit and ~CTS signal will be reset in the local MDP until the loop is established. The RDLE bit should be set before setting the RDL bit. (V.22 bis, V.22, Bell 212A/1200)
RDLE	07h:7	1	Remote Digital Loopback Response Enable. When set, control bit RDLE enables the MDP to respond to another modem's V.22 bis remote digital loopback request, thus going into loopback. When this occurs, the MDP clamps RXD to mark; resets the CTS, DSR and RLSD bits, and turns the ~CTS, ~DSR and ~RLSD signals to logic 1. The TM bit is set to inform the host of the test status. When the RDLE bit is reset, no response will be generated. (V.22 bis)
RDWK	15h:5	1	Ring Detect Wake up. When control bit RDWK is set and the MDP is in sleep mode, an incoming ring signal on the RINGD pin will bring the MDP out of sleep mode. The RINGD pin must be normally low for the RDWK function to work. (See SLEEP bit).
RI	0Fh:3	–	Ring Indicator. When set, status bit RI indicates that a ringing signal is being detected. Ringing is detected if pulses are present on the RINGD input in the 15 Hz–68 Hz frequency range. The RI bit follows the ringing signal with a 1 during the ON time and a 0 during the OFF time coincident with ~RI output signal. The decision bounds are host programmable in DSP RAM. This bit is valid only when DATA bit is reset and is not applicable in tone modes.
RIEN	1Ah:6	0	RION Enable. When control bit is a 1, the ~RI output will reflect the RION bit. When a 0, the ~RI output follows the ringing signal on the RINGD input.
RION	1Ah:5	0	Ring Indicator On. Control bit RION determines the state of the ~RI output (1 = low; 0 = high) when bit RIEN is set and the DATA bit is reset.
RLSD	0Fh:7	–	Received Line Signal Detector. When status bit RLSD is set, the MDP has finished receiving the training sequence or has turned on due to detected energy above threshold, and is receiving data. RLSD is reset when the MDP is in the idle state and during the reception of a training sequence. The RLSD threshold may be adjusted in DSP RAM.
RLSDE	03h:4	1	RLSD Enable. When control bit RLSDE is set, the ~RLSD pin reflects the RLSD bit state. When RLSDE is reset, the ~RLSD pin is clamped OFF and data is clamped to a mark regardless of the state of the RLSD bit.
RREDT	0Eh:5	–	Rate Renegotiation Detected. When set, status bit indicates a rate renegotiation sequence has been detected. RREDT will remain on until the host resets it. (V.90, K56flex, V.34, V.32 bis, V.32)

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
RREN	15h:2	0	<p>Rate Renegotiation. If control bit RREN is set in V.90, K56flex, V.34 or V.32 bis data mode, a rate negotiation sequence is initiated. RREN resets as soon as the initiation is acknowledged. The RREN bit should be used only if both the local and remote modems are V.90, K56flex, V.34 or V.32 bis. The value in CONF indicates the connected mode (E0h-F6h = V.90, 90h-9Dh = K56flex, C0h-CEh = V.34, and 7xh = V.32 bis).</p> <p>Fallback or fall-forward rate renegotiations may be accomplished in V.90/K56flex/V.34/V.32 bis mode as follows:</p> <ol style="list-style-type: none"> 1. If EARC = 0, change CONF to the required configuration code. (If EARC = 1, do not change CONF; rate renegotiations are best left to the host, not the MDP's auto rate selection). EARC should be left off once the MDP is connected and only enabled (if desired) if a retrain is detected and initiated. NOTE: Only the data rate within a mode can be changed, not the mode. Do not set the NEWC bit. 2. Set the RREN bit. <p>If the remote modem can operate at the requested rate, the configuration will be changed by the MDP to reflect the new rate after the rate renegotiation is completed. The CTS bit will be reset during the rate renegotiation and will be set again upon completion of the rate renegotiation.</p> <p>If the remote modem cannot operate at the new rate and there are no common rates between the two modems, the MDP will send a Cleardown sequence and turn off RLSD in V.32 bis, or present an ABCODE of 96h in V.90/K56flex/V.34. The CONF register will contain C0h (V.90/K56flex/V.34) or 70h (V.32 bis) to indicate that a Cleardown was accomplished.</p> <p>In order to prevent rate negotiations from colliding, the MDP will first check for a possible incoming retrain or rate renegotiation before allowing the setting of the RREN bit to be processed. This may delay the RREN request by 3-4 ms. If a valid retrain or rate renegotiation is detected, the request for a RREN will be denied and the RREN bit will be reset to 0. The MDP will then proceed with the received retrain or rate renegotiation request.</p> <p>In V.32 bis, if the rate renegotiation fails due to line conditions, the MDP will try to complete the rate change by means of a retrain.</p> <p>In V.90/K56flex/V.34, the host must check EQM and issue the retrain manually by setting the RTRN bit.</p>
RRTSE	09h:1	0	<p>Remote RTS Signaling Enable. When control bit RRTSE is set and both the RTS bit and the RTS pin are inactive, the transmitter will send a pattern (idle pattern) produced by scrambling a binary 1 with the polynomial $1+x^{-3}+x^{-7}$. If RTS is deactivated and immediately reactivated, the MDP will send approximately 144 bits of idle pattern before acknowledging the reactivation of RTS. When RRTSE is set and the RTS bit or the RTS pin is activated, the transmitter will immediately send a pattern of 8 bits (turn-on pattern) produced by scrambling a binary 0 with the polynomial $1+x^{-3}+x^{-7}$ followed by the user data. CTS is automatically delayed until the end of the 8-bit turn-on pattern. The RTS-CTS delay may be increased to allow the MDP to transmit a period of mark after the 8-bit turn-on pattern in order to give the remote modem ample time to detect the turn-on and unclamp the receive data line. When control bit RRTSE is reset, remote RTS signaling is disabled and the RTS bit and RTS pin operate normally.</p> <p>In V.22 bis/V.22 LL mode, wait until RLSD = 1, set RRTSE, then set the CC bit. (Note that the CC bit must be set in order for V.13 to function in V.22 bis/V.22 LL mode.)</p> <p>This bit is not valid in FSK modes.</p>

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description															
RSEQ	0Ch:0	0	Rate Sequence Received. When status bit RSEQ is set, the 16-bit rate sequence included in the start-up procedure has been received and is available in RAM. RSEQ will remain set until reset by the host. (V.32 bis, V.32)															
RTDET	0Eh:7	–	Retrain Detector. When set, status bit RTDET indicates that a training sequence has been detected (V.90, K56flex, V.34, V.32 bis, V.32 or V.22 bis). This bit parallels the operation of the following: <table><tr><td>Mode</td><td>Detector Bit</td></tr><tr><td>V.32 Originate</td><td>ACDET</td></tr><tr><td>V.32 Answer</td><td>AADET</td></tr><tr><td>V.22 bis</td><td>S1DET</td></tr></table>	Mode	Detector Bit	V.32 Originate	ACDET	V.32 Answer	AADET	V.22 bis	S1DET							
Mode	Detector Bit																	
V.32 Originate	ACDET																	
V.32 Answer	AADET																	
V.22 bis	S1DET																	
RTH	13h:3-2	0	Receiver Threshold. The RTH control bits select the receiver energy detector threshold according to the following codes: <table><tr><td>RTH</td><td>RLSD ON</td><td>RLSD OFF</td></tr><tr><td>0</td><td>– 43 dBm</td><td>– 48 dBm</td></tr><tr><td>1</td><td>– 33 dBm</td><td>– 38 dBm</td></tr><tr><td>2</td><td>– 26 dBm</td><td>– 31 dBm</td></tr><tr><td>3</td><td>– 16 dBm</td><td>– 21 dBm</td></tr></table>	RTH	RLSD ON	RLSD OFF	0	– 43 dBm	– 48 dBm	1	– 33 dBm	– 38 dBm	2	– 26 dBm	– 31 dBm	3	– 16 dBm	– 21 dBm
RTH	RLSD ON	RLSD OFF																
0	– 43 dBm	– 48 dBm																
1	– 33 dBm	– 38 dBm																
2	– 26 dBm	– 31 dBm																
3	– 16 dBm	– 21 dBm																
RTRN	08h:1	0	Retrain. If control bit RTRN is set in V.90, K56flex, V.34, V.32 bis, V.32, or V.22 bis data mode, a retrain sequence is initiated. RTRN resets as soon as the initiation is acknowledged. <p>Fallback or fall-forward retrains may be accomplished in V.90, K56flex, V.34, V.32 bis, V.32, or V.22 bis modes as follows:</p> <ol style="list-style-type: none">If EARC = 0, change CONF to the required configuration code. (If EARC = 1, do not change CONF). NOTE: Only the data rate within a mode can be changed, not the mode, e.g., fallback from V.32 to V.22 bis mode is not possible. Do not set the NEWC bit.Set the RTRN bit. <p>If the remote modem can operate at the requested rate, the configuration will be changed by the MDP to reflect the new rate after the retrain is completed. The CTS bit will be reset during the retrain and will be set again upon completion of the retrain. The SPEED bits will also be updated at the end of the retrain. The host may wish to clear the SPEED bits during the retrain and wait for them to be updated to signify the end of retrain.</p> <p>If the remote modem cannot operate at the new rate and there are no common rates between the two modems, the MDP will send a Cleardown sequence and turn off RLSD in V.32 bis or present an ABCODE of 96h in V.90/K56flex/V.34. The CONF register will contain C0h (V.90/K56flex/V.34) or 70h (V.32 bis/V.32) to indicate that a Cleardown was accomplished.</p> <p>If the MDP reconfigures from V.22 bis 2400 bps to V.22 1200 bps during a handshake or as a result of a retrain, the CONF register will contain 82h.</p>															

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
RTS	08h:0	0	<p>Request to Send. When control bit RTS is set, the MDP transmits any data on TXD (TPDM = 0) or TBUFFER (TPDM = 1) when CTS becomes active.</p> <p>In V.22 bis, V.22, V.23, V.21, and Bell 103 constant carrier and in V.90, K56flex, V.34, V.32 bis, and V.32 modes, RTS controls data transmission and DTR controls the carrier. For ease of use, RTS can be turned ON at the same time as DTR.</p> <p>In V.22 bis controlled carrier mode, RTS independently controls the carrier when DTR is ON. When RTS is turned ON, the MDP then transmits 270 ms of scrambled 1s before turning CTS ON.</p> <p>In V.21, V.23, V.23 HDX, and Bell 103 controlled carrier modes, RTS independently controls the carrier when DTR is ON. When RTS is turned ON, CTS is turned ON per Table 1-3.</p> <p>In V.33, V.17, V.29, V.27, and V.21 Ch 2 fax modes, RTS controls the training sequence transmission.</p> <p>The RTS bit parallels the operation of the RTS hardware control input. These inputs are ORed by the MDP. Note: Wait for TDBE = 1 before turning off RTS. (See descriptions of CTS and DTR bits.)</p>
RTSDE	02h:3	0	<p>Remote RTS Pattern Detector Enable. When control bit RTSDE is set, the remote RTS pattern detector is enabled. RTSDE is available in synchronous and asynchronous modes. This bit is not valid in FSK modes. (See RTSDET).</p>
RTSDT	0Fh:1	–	<p>Remote RTS Pattern Detected. When set, status bit RTSDT indicates that the remote RTS signal is ON, otherwise it indicates that the remote RTS signal is OFF. This status bit is valid only when RTSDE is set. This status bit should be initialized by the host upon setting RTSDE. The MDP will automatically activate/de-activate the local RLSD signal in response to a change in the remote RTS signal. Detection is available in synchronous and asynchronous modes. This bit is not valid in FSK modes.</p>
RXFNE	0Ch:1	-	<p>Receiver FIFO Not Empty. When set, status bit RXFNE indicates that the receiver FIFO contains one or more bytes of data. When reset, bit RXFNE indicates that the receiver FIFO is empty. As long as RXFNE = 1 or RDBF = 1, there is receive data to be read. The host may use either bit. (TPDM = 1, FIFOEN = 1)</p>
RXHF	01h:1	0	<p>Receiver FIFO Half Full. When set, status bit RXHF indicates that there are 8 or more bytes in the 16-byte Receiver FIFO buffer. When reset, RXHF indicates that there are less than 8 bytes in the Receiver FIFO buffer. (TPDM = 1)</p> <p>An interrupt mask is available to allow an interrupt request to be generated when RXHF transitions from reset to set or from set to reset (the interrupt will occur as the FIFO fills above the half-full point and as the FIFO empties below the half-full point) (see Function 17 in Section 4).</p>
RXP	01h:0	0	<p>Received Parity Bit. This status bit is only valid when parity is enabled (PEN = 1), and word size is set for 8 bits per character (WDSZ = 11). In this case, the parity bit received (or ninth data bit) will be available at this location. The host must read this bit before reading the received data buffer (RBUFFER).</p>
RXV	11h:3	0	<p>Receive Voice. In a tone mode or DTMF receive mode (CONF = ACh, 80h, 81h, 83h, or 86h); control bit RXV = 1 selects receive voice ADPCM mode (CDEN = 1) or receive voice pass-through mode (CDEN = 0); RXV = 0 disables receive voice mode.</p> <p>In ADPCM receive mode (CDEN = 1), the MDP performs ADPCM coding. The coder output is placed into the Voice Receive Buffer (VBUFR).</p> <p>In receive voice pass-through mode (CDEN = 0), the host can directly access to the A/D converter.</p> <p>The host can obtain 16-bit voice samples from VBUFR at the selected sample rate (7200 Hz default). VBUFR reflects the receive voice sample when bit RDBF is set. (See VBUFR.)</p>

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
S1DET	0Dh:5	–	S1 Detector. When set, status bit S1DET indicates that a V.22 bis S1 sequence has been detected. This bit is reset by the MDP at the end of the S1 sequence. (V.22 bis)
S511	02h:5	0	Send 511. When set, control bit S511 instructs the MDP to generate and transmit a 511 pattern in the current configuration. If bit V54T, V54P, or V54A is set while bit S511 is set, the 511 pattern will be temporarily interrupted in order to transmit the chosen V54 sequence. For the MDP to detect the 511 pattern, the host must first set up the sync time-out counter at address 0A5h using RAM access method 1 (see 4.2). The most significant bit enables or disables the 511 detection (1 = on) and bits 0-6 represent the sync time-out in byte times. A value of FFh in this location will enable the 511 detection and allow the maximum sync time-out. The 16-bit value read from address 0A7h contains the error count. Bits V54TE, V54PE, and V54AE must be reset in order for the 511 detection to function. (Synchronous modes only.)
SCIBE	1Ah:1	–	Secondary Channel Input Buffer Empty. When set, status bit SCIBE indicates that the secondary channel transmit buffer (SECTXB) is empty and ready for the next byte. The host must reset SCIBE after writing a new byte in SECTXB. See SECEN. (See SECEN.) (V.34, V.32 bis, V.32)
SCOBF	1Ah:2	–	Secondary Channel Output Buffer Full. When set, status bit SCOBF indicates that the secondary channel receive buffer (SECRXB) is full. The host must reset SCOBF after reading SECRXB. See SECEN. (V.34, V.32 bis, V.32)
SCR1	0Dh:4	–	Scrambled Ones Detector. When set, status bit SCR1 indicates that V.22 bis scrambled 1s have been detected during handshake. This bit is reset at the end of the scrambled 1s sequence. (V.22 bis, V.22, Bell 212)
SDET	0Ch:3	–	S Detector. When set, status bit SDET indicates that a S sequence has been detected. This bit is reset by the MDP at the end of the S sequence. (V.34, V.32 bis, V.32)
SECEN	1Ah:0	0	Secondary Channel Enable. When control bit SECEN is set the secondary channel is enabled. When SECEN is reset the secondary channel is disabled. Bit SECEN may be set in idle mode or during the V.32 bis/V.32 handshake prior to RLSD turning on. The secondary channel may be turned on or off in data mode by setting or resetting the SECEN bit and performing a retrain. (V.34 or V.32 bis/V.32 at 7200 bps or above.)
SECRXB	16h:7-0	–	Secondary Receive Buffer. The host obtains secondary channel from the MDP receiver by reading a data byte from the SECRXB when bit SCOBF is set. (V.34, V.32 bis, V.32) SECRXB is also used to convey V.8, V.90, K56flex, and V.34 handshake status (see Section 9.4). SECRXB is also used in voice mode (see RXV).
SECTXB	17h:7-0	–	Secondary Transmit Buffer. The host conveys secondary channel output data to the transmitter by writing a data byte to the SECTXB when bit SCIBE is set. SECTXB is also used to convey V.8, V.90, K56flex, and V.34 handshake status (see Section 9.4). (V.90, K56flex, V.34, V.32 bis, V.32) In the transmit voice mode with the FIFO not enabled, SECTXB contains the low byte and VBUFT contains the high byte of the transmit voice sample. (See TXV and FIFOEN.) (Voice transmit mode).
SEPT	03h:6	0	Short Echo Protector Tone. When control bit SEPT is set, the echo protector tone duration is 30 ms; when reset, the echo protector tone duration is 185 ms. (V.33, V.17, V.29, V.27)
SFRES	1Ah:7	0	Soft Reset. When control bit SFRES is set to a 1, the MDP will perform power-on reset processing. The NEWC bit will be reset to a 0 by the MDP upon completion of the reset processing. NEWC must be set to initiate the reset. Wait for NEWC to clear plus 10 ms before accessing the MDP.

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description																																						
SLEEP	15h:7	0	<p>Sleep Mode. When control bit SLEEP is set and the STOP bit is reset, the MDP is placed in Sleep mode for reduced power consumption and the SLEEP pin is driven low. The MDP can be awakened only if bit RDWK is set and a ring is detected, and/or HWRWK is set and a host write occurs (see HWRWK bit). If both RDWK and HWRWK are reset, only a power-on-reset will bring the MDP out of sleep mode. The MDP is reset upon wake up.</p> <p>When the SLEEP bit is set and the STOP bit is set, the MDP is placed in Stop mode (see STOP bit description).</p>																																						
SNDET	0Ch:2	–	<p>S Negative Detector. When set, status bit SNDET indicates that a ~S sequence has been detected. This bit is reset at the end of the ~S sequence. (V.34, V.32 bis, V.32)</p>																																						
SPEED	0Eh:4-0	–	<p>Speed Indication. In non-V.34 modes, the SPEED status bits indicate the receiver's and transmitter's data rate at the completion of a handshake.</p> <p>In V.90, K56flex and V.34 asymmetric modes, the SPEED status bits indicate the transmitter's data rate and the CONF bits indicate the receiver's data rate at the completion of a handshake.</p> <table><thead><tr><th>SPEED (Hex)</th><th>Data Rate (bps)</th></tr></thead><tbody><tr><td>0</td><td>0–300</td></tr><tr><td>1</td><td>600</td></tr><tr><td>2</td><td>1200</td></tr><tr><td>3</td><td>2400</td></tr><tr><td>4</td><td>4800</td></tr><tr><td>5</td><td>9600</td></tr><tr><td>6</td><td>12000</td></tr><tr><td>7</td><td>14400</td></tr><tr><td>8</td><td>7200</td></tr><tr><td>9</td><td>16800</td></tr><tr><td>A</td><td>19200</td></tr><tr><td>B</td><td>21600</td></tr><tr><td>C</td><td>24000</td></tr><tr><td>D</td><td>26400</td></tr><tr><td>E</td><td>28800</td></tr><tr><td>F</td><td>31200</td></tr><tr><td>10</td><td>33600</td></tr><tr><td>11-1F</td><td>Reserved</td></tr></tbody></table> <p>Also, see Function 1 in Section 4 for V.34.</p>	SPEED (Hex)	Data Rate (bps)	0	0–300	1	600	2	1200	3	2400	4	4800	5	9600	6	12000	7	14400	8	7200	9	16800	A	19200	B	21600	C	24000	D	26400	E	28800	F	31200	10	33600	11-1F	Reserved

SQDIS	02h:6	0	<p>Squarer Disable (Tone Detector C). When control bit SQDIS is set, the squarer in front of tone detector C is disabled; when reset, the squarer is enabled. Disabling the squarer cascades the prefilter and filter C creating an 8th-order filter.</p>																																						

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description																		
SRCEN	03h:5	0	<p>Secondary Rate Change Enable. The MDP has a method of performing rate changes in V.34 which causes no interruption of primary data. This is a proprietary method and will only work if both modems are Rockwell data pumps. This compatibility is enforced by communicating the seamless rate change capability during the handshake. The rate change request is communicated over the modem's secondary channel.</p> <p>The method to enable Seamless Rate Changes is:</p> <ol style="list-style-type: none">1. Enable the seamless rate change indicator by setting bits 0 and 1 of address 3A5h. The status indicating remote seamless rate change capability is reflected in bit 103h:7.2. Set bit SECEN.3. Enable both asymmetric data rates and Framed Secondary Channel (bits 13Fh:6 and 39Bh:0, respectively). Asymmetric mode must be used for seamless rate change.4. Make a connection. <p>All RAM accesses are 8 bit.</p> <p>Check bit 103h:7 after the connection is complete. If set, the remote modem is capable of performing seamless rate changes. If not set, seamless rate changes should not be attempted.</p> <p>To invoke a seamless rate change, change CONF to the desired receive data rate and then set SRCEN. The CONF register and speed bits will be updated with the new data rate at the completion of the rate change.</p> <p>This feature should be used at the user's discretion.</p>																		
STB	06h:2	0	<p>Stop Bit Number. When control bit STB is reset, one stop bit is selected in asynchronous mode; when set, two stop bits are selected. This bit must be configured appropriately before the ASYN bit changes from a 0 to a 1 for asynchronous mode. (V.90, K56flex, V.34, V.32 bis, V.32, V.22, V.22 bis, Bell 212A)</p>																		
STOFF	05h:1	0	<p>Soft Turn Off. When control bit STOFF is set, the transmitter sends a tone at the end of a transmission in V.23, V.21, and Bell 103 configurations. This tone is detected as a mark frequency at the receiver. The soft turn off tone frequencies and durations are as follows:</p> <table><thead><tr><th>Configuration</th><th>Frequency (Hz)</th><th>Duration (ms)</th></tr></thead><tbody><tr><td>V.23/1200</td><td>900</td><td>7</td></tr><tr><td>V.21 Originate</td><td>880</td><td>30</td></tr><tr><td>V.21 Answer</td><td>1550</td><td>30</td></tr><tr><td>Bell 103 Originate</td><td>1370</td><td>30</td></tr><tr><td>Bell 103 Answer</td><td>2325</td><td>30</td></tr></tbody></table>	Configuration	Frequency (Hz)	Duration (ms)	V.23/1200	900	7	V.21 Originate	880	30	V.21 Answer	1550	30	Bell 103 Originate	1370	30	Bell 103 Answer	2325	30
Configuration	Frequency (Hz)	Duration (ms)																			
V.23/1200	900	7																			
V.21 Originate	880	30																			
V.21 Answer	1550	30																			
Bell 103 Originate	1370	30																			
Bell 103 Answer	2325	30																			
STOP	15h:6	0	<p>Stop Mode. When control bit STOP is set and the SLEEP bit is set, the MDP is placed in the lowest power consumption mode. All clock activity ceases in STOP mode and the crystal oscillator is turned off. A hardware reset is required to wake the MDP from STOP mode.</p>																		

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
STRN	04h:0	0	Short Train Select. When a V.17 or V.27 configuration is selected in CONF, control bit STRN selects the training mode (1 = short train; 0 = long train). (V.17, V.27 ter) STRN may be set only after the completion of a successful long train. STRN may be set or reset during data mode (RLSD on) or anytime before the start of the following training sequence. Setting STRN will inhibit the equalizer taps from being reset during the following short train thus allowing for a fast adaptation. A short train may be received only when STRN is set. Once STRN is set, the DATA bit must remain set and the only allowable configuration between V.17 and V.27 that will not alter the taps is V.21 Channel 2. (V.17, V.27 ter)
SYNCD	0Ah:0	0	Sync Pattern Detected. When set, status bit SYNCD indicates that SDLC/HDLC flags (7E pattern) are being detected. When reset, the 7E pattern is not being detected. SYNCD is cleared when the first data byte of the current frame is received in RBUFFER. This bit is valid only in SDLC/HDLC mode (HDLC = 1). In voice receive mode, SYNCD = 1 is used to trigger on the first low byte (see Figure 11-3).
TBUFFER	10h:7-0	00	Transmit Data Buffer. The host conveys output data to the transmitter in the parallel mode by writing a data byte to the TBUFFER. Parallel data mode is available in both synchronous and asynchronous modes. The data is transmitted bit 0 first (see TDBE). NOTE: Do not read TBUFFER during data mode. RTS must = 1.
TDE	02h:7	1	Tone Detectors Enable. When control bit TDE is set, tone detectors A, B, and C are enabled; when reset, tone detectors are disabled.
TDBE	1Eh:3	–	Transmit Data Buffer Empty. When set, status bit TDBE signifies that the MDP has read TBUFFER (10h) and the host can write new data into TBUFFER. This condition can also cause IRQ to be asserted. The host writing to TBUFFER resets the TDBE and TDBIA bits. If the host does not write new data into TBUFFER, the MDP sends mark. TDBE must be a 1 before switching between synchronous, asynchronous, or HDLC modes. CTS must be on before data is loaded into TBUFFER. If FIFOEN is set, TDBE, when set, indicates that the transmit FIFO is empty (128-byte extension disabled) or that more data may continue to be written to TBUFFER (128-byte extension enabled). (See TDBIE and TDBIA.)
TDBIA	1Eh:7	–	Transmit Data Buffer Interrupt Active. When the transmit data buffer interrupt is enabled (TDBIE is set) and register 10 is empty (TDBE is set), the MDP asserts IRQ and sets status bit TDBIA to indicate that TDBE being set caused the interrupt. The host writing to register 10 resets the TDBIA bit and clears the interrupt request due to TDBE. (See TDBIE and TDBE.)
TDBIE	1Eh:5	0	Transmit Data Buffer Interrupt Enable. When control bit TDBIE is set (interrupt enabled), the MDP will assert IRQ and set the TDBIA bit when TDBE is set by the MDP. When TDBIE is reset (interrupt disabled), TDBE has no effect on IRQ or TDBIA. (See TDBE and TDBIA.)

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description																																																			
TEOF	11h:1	0	HDLC Transmit End of Frame. When operating in HDLC with FIFOEN = 1, the host must set control bit TEOF to inform the transmitter that the corresponding data is the last byte in a frame. TEOF must be set prior to loading the last byte in TBUFFER. The host must reset TEOF prior to loading the next data byte. In voice transmit mode, TEOF is used to sync the ADPCM decoder (see Section 11). (HDLC = 1, TPDM = 1, FIFOEN = 1)																																																			
TLVL	13h:7-4	9	<p>Transmit Level. The TLVL code selects the transmitter analog output level at the TXA pin as follows:</p> <table><thead><tr><th>TLVL Code (Hex)</th><th>TX Output Level (dBm ±0.5 dB) [VAA = +3.3V]</th><th>TX Output Level (dBm ±0.5 dB) [VAA = +5V]</th></tr></thead><tbody><tr><td>0</td><td>-4.0</td><td>0</td></tr><tr><td>1</td><td>-5.0</td><td>-1.0</td></tr><tr><td>2</td><td>-6.0</td><td>-2.0</td></tr><tr><td>3</td><td>-7.0</td><td>-3.0</td></tr><tr><td>4</td><td>-8.0</td><td>-4.0</td></tr><tr><td>5</td><td>-9.0</td><td>-5.0</td></tr><tr><td>6</td><td>-10.0</td><td>-6.0</td></tr><tr><td>7</td><td>-11.0</td><td>-7.0</td></tr><tr><td>8</td><td>-12.0</td><td>-8.0</td></tr><tr><td>9</td><td>-13.0</td><td>-9.0</td></tr><tr><td>A</td><td>-14.0</td><td>-10.0</td></tr><tr><td>B</td><td>-15.0</td><td>-11.0</td></tr><tr><td>C</td><td>-16.0</td><td>-12.0</td></tr><tr><td>D</td><td>-17.0</td><td>-13.0</td></tr><tr><td>E</td><td>-18.0</td><td>-14.0</td></tr><tr><td>F</td><td>-19.0</td><td>-15.0</td></tr></tbody></table> <p>The host can fine tune the transmit level by changing a value in DSP RAM. Not applicable to Speakerphone Mode (CONF = ACh).</p>	TLVL Code (Hex)	TX Output Level (dBm ±0.5 dB) [VAA = +3.3V]	TX Output Level (dBm ±0.5 dB) [VAA = +5V]	0	-4.0	0	1	-5.0	-1.0	2	-6.0	-2.0	3	-7.0	-3.0	4	-8.0	-4.0	5	-9.0	-5.0	6	-10.0	-6.0	7	-11.0	-7.0	8	-12.0	-8.0	9	-13.0	-9.0	A	-14.0	-10.0	B	-15.0	-11.0	C	-16.0	-12.0	D	-17.0	-13.0	E	-18.0	-14.0	F	-19.0	-15.0

E	-18.0	-14.0																																																				
F	-19.0	-15.0																																																				

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description								
TM	0Fh:2	–	Test Mode. When set, status bit TM indicates that the MDP is in RDL test mode. The TM bit will be set when RLSD turns off at the start of RDL, and will reset less than 100 ms prior to RLSD turning back on at the end of RDL. (V.22 bis, V.22, Bell 212A)								
TONEA	0Bh:7	–	Tone A Detected. When set, status bit TONEA indicates that energy is present on the line within the tone detector A passband and above its threshold. The bandpass filter coefficients are host programmable in DSP RAM.								
TONEB	0Bh:6	–	Tone B Detected. When set, status bit TONEB indicates that energy is present on the line within the tone detector B passband and above its threshold. The bandpass filter coefficients are host programmable in DSP RAM.								
TONEC	0Bh:5	–	Tone C Detected. When set, status bit TONEC indicates that energy is present on the line within the tone detector C passband and above its threshold. The bandpass filter coefficients are host programmable in DSP RAM. The TONEC filter is preceded by a squarer in order to facilitate detection of difference tones. This squarer may be disabled with the SQDIS bit (see SQDIS bit).								
TPDM	08h:6	0	Transmitter Parallel Data Mode. When control bit TPDM is set, the MDP accepts data for transmission from the TBUFFER (10h) rather than the TXD input. (See TDBE and RTS.) Note: The TPDM bit must be set to a 1 in HDLC mode and should always be set prior to setting DTR and RTS. (HDLC bit = 1).								
TXCLK	13h:1-0	0	Transmit Clock Select. The TXCLK control bits designate the origin of the transmitter data clock. NEWC must be set to initiate TXCLK change. The TXCLK encoding is: <table><tr><td>TXCLK</td><td>Transmit Clock</td></tr><tr><td>0</td><td>Internal</td></tr><tr><td>2</td><td>External (XTCLK)</td></tr><tr><td>3</td><td>Slave (~RDCLK)</td></tr></table> When the external clock is selected, an external clock must be supplied to the XTCLK input pin. The external clock signal must have a duty cycle of 50% and must be within ±0.01% of the nominal TDCLK frequency (the actual frequency of TDCLK as measured when internal clock is selected). TDCLK will be phase locked to XTCLK when the external clock option is selected. When the slave clock is selected, the transmitter clock (TDCLK) is phase locked to the receiver clock (~RDCLK).	TXCLK	Transmit Clock	0	Internal	2	External (XTCLK)	3	Slave (~RDCLK)
TXCLK	Transmit Clock										
0	Internal										
2	External (XTCLK)										
3	Slave (~RDCLK)										
TXFNF	0Dh:1	-	Transmitter FIFO Not Full. When set, status bit TXFNF indicates that the transmitter FIFO is not full and the host may continue to write data to the TBUFFER. When reset, TXFNF indicates that the transmitter FIFO is full. (TPDM = 1, FIFOEN = 1)								
TXHF	01h:2	0	Transmitter FIFO Half Full. When set, status bit TXHF indicates that there are 8 or more bytes in the 16-byte Transmitter FIFO buffer. When reset, TXHF indicates that there are less than 8 bytes in the Transmitter FIFO buffer. (TPDM = 1, FIFOEN = 1) An interrupt mask is available to allow an interrupt request to be generated when TXHF transitions from reset to set or from set to reset (the interrupt will occur as the FIFO fills above the half-full point and as it empties below the half-full point) (see Section 4, Function 17).								
TXP	11h:0	0	Transmit Parity Bit (or 9th Data Bit). Control bit TXP contains the stuffed parity bit (or ninth data bit) for transmission when parity is enabled (PEN = 1), stuff parity is selected (PARSL = 00), and word size is set for 8 bits per character (WDSZ = 11). The host must load the stuffed parity bit (or 9th data bit) into TXP before loading the other 8 bits of data in TBUFFER.								

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description
TXSQ	05h:4	0	<p>Transmitter Squelch. When control bit TXSQ is set, the transmitter analog output is squelched. All other transmitter functions continue as normal. When TXSQ is reset, the transmitter output functions normally.</p> <p>It is recommended that TXSQ be set while in the fax receive mode.</p>
TXV	11h:4	0	<p>Transmit Voice. In a tone mode or DTMF receive mode (CONF = ACh, 80h, 81h, 83h, or 86h), control bit TXV = 1 selects transmit voice ADPCM mode (DCDEN = 1) or transmit voice pass-through mode (DCDEN = 0); TXV = 0 disables transmit voice mode.</p> <p>In transmit voice ADPCM mode (DCDEN = 1), the MDP performs ADPCM decoding on the contents of the Voice Transmit Buffer (VBUFT).</p> <p>In transmit voice pass-through mode (DCDEN = 0), the host can directly access to the D/A converter.</p> <p>The host may send voice samples to the MDP at the selected sample rate (7200 Hz default). The MDP will accept voice samples from VBUFT when the FIFO is enabled or from VBUFT (high byte) and SECTXB (low byte) when the FIFO is not enabled. (See FIFOEN and VBUFT.)</p>
U1DET	0Dh:3	–	<p>Unscrambled 1s Detector. When set, status bit U1DET indicates that V.22 bis unscrambled 1s sequence has been detected. This bit is reset by the MDP at the end of the unscrambled 1s sequence. U1DET is not active when DATA is reset. (V.22 bis)</p>
VAGC	04h:2	0	<p>Voice AGC. In receive voice mode (RXV = 1), the host can enable (VAGC = 1) or disable (VAGC = 0) the voice AGC.</p>
VINIT	05h:5	0	<p>Voice Initiate. In voice configurations, control bit VINIT, when set to a 1, invokes voice operation after TXV, RXV, and other voice options are set. VINIT clears automatically after voice initiation is complete.</p>
V21S	08h:5	0	<p>V21 Synchronous. In V.21 configuration (CONF = A0h), control bit V21S selects either synchronous (V21S = 1) or asynchronous (V21S = 0) mode.</p> <p>In V.21 synchronous mode, a synchronous transmit clock is provided on the TDCLK pin and a synchronous receive clock is provided on the ~RDCLK pin. During transmit, synchronous data may be applied in either serial or parallel form depending on the TPDM bit. During receive, synchronous data is output in both serial or parallel form.</p> <p>NEWC must be set immediately after changing the V21S bit to initiate the mode change.</p> <p>Note: Do not set this bit in V.21 Channel 2 (CONF = A8h).</p>
V23HDX	11h:2	0	<p>V.23 Half Duplex. When control bit V23HDX is set, the MDP operates in V.23 /1200 half duplex. The transmitter and receiver must be set to the same V.23 configuration, 1200 bps (CONF = A4h). Carrier is under RTS control and DTR must be on. The RTS-CTS delay is adjustable in RAM.</p>
V54A	08h:3	0	<p>V.54 Acknowledgment Signaling. When control bit V54A is set, and provided that CTS is ON, the transmitter will send a pattern of 1948 bits produced by scrambling a binary 1 with the polynomial $1+x^{-4}+x^{-7}$ in accordance with ITU-T Recommendation V.54. The transmission will be at the modem data signaling rate. When transmission of the signaling pattern is complete, V54A is automatically reset by the MDP. V.54 signaling pattern detection is available in both synchronous and asynchronous modes. (Not valid in FSK modes.)</p>
V54AE	02h:1	0	<p>V.54 Acknowledgment Phase Detector Enable. When control bit V54AE is set, the V.54 acknowledgment phase detector is enabled in the receiver. V.54 signaling pattern detection is available in both synchronous and asynchronous modes. (See V54DT). (Not valid in FSK modes.)</p>

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description															
V54DT	0Fh:0	0	V.54 Pattern Detected. When set, status bit V54DT indicates that one of the three V.54 patterns is being detected. Only one of the three detector enabling bits (V54PE, V54AE or V54TE) must be set by the host at any given time. V54DT should be reset by the host after detection. V.54 signaling pattern detection is available in both synchronous and asynchronous modes. (Not valid in FSK modes.)															
V54P	08h:2	0	V.54 Preparatory Signaling. When control bit V54P is set and CTS is ON, the transmitter will send a pattern of 2048 bits produced by scrambling a binary 0 with the polynomial $1+x^{-4}+x^{-7}$ in accordance with ITU-T Recommendation V.54. The transmission will be at the modem data signaling rate. When the transmission of the signaling pattern is complete, V54P is automatically reset by the MDP. V.54 signaling pattern detection is available in both synchronous and asynchronous modes. (Not valid in FSK modes.)															
V54PE	02h:0	0	V.54 Preparatory Phase Detector Enable. When control bit V54PE is set, the V.54 preparatory phase detector is enabled in the receiver. V.54 signaling pattern detection is available in both synchronous and asynchronous modes. (See V54DT). (Not valid in FSK modes.)															
V54T	08h:4	0	V.54 Termination Signaling. When control bit V54T is set, and provided that CTS is ON, the transmitter will send a pattern of 8192 bits produced by scrambling a binary 1 with the polynomial $1+x^{-4}+x^{-7}$ followed by 64 binary 1s in accordance with ITU-T Recommendation V.54. The transmission will be at the modem signaling rate. When transmission of the signaling pattern is complete, V54T is automatically reset by the DSP. V.54 signaling pattern detection is available in both synchronous and asynchronous modes. (Not valid in FSK modes.)															
V54TE	02h:2	0	V.54 Termination Phase Detector Enable. When control bit V54TE is set, the V.54 termination phase detector is enabled in the receiver. V.54 signaling pattern detection is available in both synchronous and asynchronous modes. (See V54DT). (Not valid in FSK modes.)															
VBUFR	00h:7-0	–	Voice Receive Buffer. In voice receive mode (RXV = 1), VBUFR contains one of two consecutive bytes of the 16-bit output voice sample. The first byte read is the low byte; the second byte read is the high byte. (See RXV.) (Receive voice only.)															
VBUFT	10h:7-0	–	Voice Transmit Buffer. In voice transmit mode (TXV = 1), VBUFT contains one of two consecutive bytes of the 16-bit input voice sample. The first byte written is the low byte; the second byte written is the high byte. When the FIFO is not enabled in the voice transmit mode, VBUFT contains the high byte of the 16-bit input voice sample while SECTXB contains the low byte of the 16-bit input voice sample. (See TXV and FIFOEN.) (Transmit voice only.)															
VOLUME	01h:7-6	0	Volume Control. The encoded VOLUME control bits select speaker off or one of three volume attenuation levels (at RIN) as follows: <table><thead><tr><th>B7</th><th>B6</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>0</td><td>Speaker off</td></tr><tr><td>1</td><td>0</td><td>Speaker attenuation = 0 dB (high volume)</td></tr><tr><td>0</td><td>1</td><td>Speaker attenuation = 6 dB (medium volume)</td></tr><tr><td>1</td><td>1</td><td>Speaker attenuation = 12 dB (low volume)</td></tr></tbody></table> The SPKMD output is enabled by setting bit 1 of RAM address 3CFh (8-bit address) and setting the VOLUME bits to 10. The analog SPK output is disabled when the SPKMD output is enabled.	B7	B6	Description	0	0	Speaker off	1	0	Speaker attenuation = 0 dB (high volume)	0	1	Speaker attenuation = 6 dB (medium volume)	1	1	Speaker attenuation = 12 dB (low volume)
B7	B6	Description																
0	0	Speaker off																
1	0	Speaker attenuation = 0 dB (high volume)																
0	1	Speaker attenuation = 6 dB (medium volume)																
1	1	Speaker attenuation = 12 dB (low volume)																

Table 3-1. MDP Interface Memory Bit Definitions (Cont'd)

Mnemonic	Location	Default	Name/Description															
VPAUSE	01h:5	0	Voice Pause. Control bit VPAUSE enables (1) or disables (0) the voice “pause.” When VPAUSE is enabled, voice data is not output to the host.															
WDSZ	06h:1-0	0	Data Word Size. The WDSZ field sets the number of data bits per character in asynchronous mode as follows (V.90, K56flex, V.34, V.32 bis, V.32, V.22, V.22 bis, Bell 212A): <table><tr><th>B1</th><th>B0</th><th>Data Bits/Character</th></tr><tr><td>0</td><td>0</td><td>5</td></tr><tr><td>1</td><td>0</td><td>6</td></tr><tr><td>0</td><td>1</td><td>7</td></tr><tr><td>1</td><td>1</td><td>8</td></tr></table> <p>These bits must be configured appropriately before the ASYN bit changes from a 0 to a 1 for asynchronous mode.</p>	B1	B0	Data Bits/Character	0	0	5	1	0	6	0	1	7	1	1	8
B1	B0	Data Bits/Character																
0	0	5																
1	0	6																
0	1	7																
1	1	8																

Table 3-2. ABCODE Error Code Definitions

Value (Hex)	Description
01	FED turned off while waiting to get into round trip delay estimate (RTDE)
10	Unexpected E-sequence, do retrain
11	Timed out in rate renegotiation
21	Timed out waiting for INFO0
22	Checksum error in INFO0
23	Timed out waiting for tone A or B
24	Timed out waiting for first phase reversal
25	Timed out waiting for probing cut-off tone
26	Timed out waiting for second phase reversal
27	Timed out waiting for end of probing
28	Timed out waiting for third phase reversal
29	Timed out waiting for INFO1
2A	Checksum error in INFO1
2B	Send repeated INFO0
2C	Found unexpected INFO0
81	FED turned off during RTDE
82	Lost track of AC/AA/CA/CC during RTDE
84	Timed out waiting for S sequence, 1st ORG
85	Timed out waiting for S sequence, 2nd ORG
86	Timed out waiting for S sequence, 1st ANS
8C	FED turned off during TRN-sequence, 1st ORG
8D	FED turned off during TRN-sequence, 2nd ORG
8E	FED turned off during TRN-sequence, 1st ANS
90	R1 not detected
91	R2 not detected
92	R3 not detected
93	R4/R5 not detected
94	Timed out looking for end of S-seq, 1st ORG
95	Timed out looking for end of S-seq, ANS
96	Received rate sequence called for Cleardown
97	E-sequence not detected
C0	Problem with S-sequence in EC-training signal
C1	FED turned off during S-sequence in EC-training signal
C2	S-sequence turned off before expected in phase 3
C3	Timed out waiting for S-Sbar in phase 3
C4	Timed out waiting for S-Sbar in phase 3
C5	Timed out waiting for S in phase 3
C6	J-sequence not detected in phase 3

Table 3-2. ABCODE Error Code Definitions (Cont'd)

Value (Hex)	Description
D0	Problem with S-sequence in phase 4
D1	FED turned off during S-sequence in phase 4
D2	S-sequence turned off before expected in phase 4
D3	Timed out waiting for S-Sbar in phase 4
D4	Timed out waiting for S-Sbar in phase 4
D5	Timed out waiting for S in phase 4
D6	Timed out waiting for MP
D7	Timed out waiting for MP'
D8	Timed out waiting for E
D9	JP-sequence not detected
DA	Timed out in transmitter rate renegotiation
DB	Reserved
DC	Timed out looking for energy
DD	Timed out in phase 3
E2	Retrain detected during phase 2
E3	Retrain detected during phase 3
E4	Retrain detected during phase 4
FE	DTR turned off during training
FF	Transmitter abort

This page is intentionally blank.

4. DSP RAM ACCESS

The MDP DSP contains a 16-bit wide random access memory (RAM). The host processor can access (read or write) the RAM through a 12-bit memory address in registers 1D and 1C.

4.1 INTERFACE MEMORY ACCESS TO DSP RAM

The interface memory acts as an intermediary during host to DSP RAM or DSP RAM to host data exchanges. The address stored in interface memory RAM address registers MEADDH and MEADDL by the host is the DSP RAM address for data access. The data is transferred through data registers MEDAM and MEDAL.

One or two bytes (1 byte = 8 bits) are transferred between DSP RAM and DSP interface memory once each device cycle. The DSP operates at a 7200 Hz sample rate.

The RAM access bit (MEACC) in the interface memory instructs the DSP to access the RAM. The transfer is initiated by the host setting the MEACC bit. The DSP tests this bit each sample period.

4.1.1 RAM Access Methods

RAM is accessed using one of four methods:

Method 1: 8-bit Read - 8-bit Write

Parameters transferred under the first method have only 8 bits of significance. The data is written to and read from MEDAL. Data in MEDAM is ignored.

Method 2: 16-bit Read - 8-bit Write

Parameters transferred using the second method have 16 bits of significance but can be written only 8 bits at a time. These parameters have two access codes associated with them, one for the least significant 8-bits and one for the most significant 8 bits. The host need read only the low address to obtain both the most significant and the least significant bytes of the data if the two access codes are in consecutive order.

Method 3: 16-bit Read - 16-bit Write

Parameters transferred using the third method involve 16-bit read or write operations using one access code.

Method 4: 16-bit Read Only (DDP Diagnostics)

Finally, all diagnostic read operations using the fourth method use only one access code. Data is read from MEDAM and MEDAL.

4.1.2 RAM Parameters

The parameters available in DSP RAM are listed in Table 4-1.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Table 4-1. MDP Interface Memory RAM Addresses

No.	Function	Method	Address (Hex)
1	K56flex/V.34 Transmitter and K56flex/V.34 Receiver Speeds		
	K56flex/V.34 Transmitter Speed	1	2E5
	K56flex/V.34 Receiver Speed	1	2E4
2	Rate Sequence		
	Received R	4	208
	Received E	4	20A
	Transmitted R	2 (RO)	205, 204 (see Note 1)
	Transmitted E	2 (RO)	207, 206 (see Note 1)
	V.32/V.32 bis R1 Mask	2	2C1, 2C0 (see Note 1)
	V.32/V.32 bis R2 Mask	2	2C3, 2C2 (see Note 1)
	V.32 bis R4 Mask	2	2C5, 2C4 (see Note 1)
	V.32 bis R5 Mask	2	2C7, 2C6 (see Note 1)
	V.33 R33 Mask	2	2C9, 2C8 (see Note 1)
3	DTMF Tone Duration	1	2DB, 218 (see Note 1)
4	DTMF Interdigit Delay	1	2DC, 219 (see Note 1)
5	DTMF Low Band Power Level	2	29C, 29B (see Note 1)
6	DTMF High Band Power Level	2	29E, 29D (see Note 1)
7	Pulse Relay Make Time	1	22C
8	Pulse Relay Break Time	1	21C
9	Pulse Interdigit Delay	2	21B, 21A
10	Calling Tone On Time	1	2D9, 290 (see Note 1)
11	Calling Tone Off Time	1	2DA, 291 (see Note 1)
12	Transmitter Output Level Gain (G)		
	Transmitter Output Level Gain (G) - All Modes	2	3DB, 3DA
	Transmitter Output Level Gain (G) - FSK Modes	3	B57
13	Dual Tone 1 Frequency	2	281, 280 (see Note 1)
14	Dual Tone 2 Frequency	2	283, 282 (see Note 1)
15	Dual Tone 1 Power Level	2	285, 284 (see Note 1)
16	Dual Tone 2 Power Level	2	287, 286 (see Note 1)
17	New Status (NEWS) Masking Registers		
	Masking Register for 01	1	247

Table 4-1. MDP Interface Memory RAM Addresses (Cont'd)

No.	Function	Method	Address (Hex)
100	Minimum On Time (DTMF)	3	E96
101	Minimum Off Time (DTMF)	3	C96
102	Minimum Cycle Time (DTMF)	3	D96
103	Minimum Dropout Time (DTMF)	3	F96
104	Maximum Speech Energy (DTMF)	3	E95
105	Frequency Deviation, Low Group (DTMF)	3	C94
106	Frequency Deviation, High Group (DTMF)	3	E94
107	Negative Twist Control, TWIST4 (DTMF)	3	D95
108	Positive Twist Control, TWIST8 (DTMF)	3	C95
109	Maximum Energy Hit Time (DTMF)	3	E87
110	ADC Speech Sample Scaling Parameter, ADCS (ADPCM)	3	F21

Notes:

1. High address = MSB of data; low address = LSB of data.
2. The host may access only the X or Y data on any given read cycle, i.e., X and Y data cannot be accessed simultaneously.
3. RO = read-only.

4.2 HOST DSP READ AND WRITE PROCEDURES

DSP RAM Write Procedure

1. Set MEMW to inform the DSP that a RAM write will occur when MEACC is set.
2. Load the RAM address into the MEADDH and MEADDL registers.
3. Write the desired data into the interface memory RAM data registers MEDAM and/or MEDAL.
4. Set MEACC to signal the DSP to perform the RAM write.
5. When the DSP has transferred the contents of the interface memory RAM data registers into RAM, the MDP resets the MEACC bit and sets the NEWS bit to indicate DSP RAM write completion. If the NSIE bit is a 1, IRQ is asserted and NSIA is set to inform the host that setting of the NEWS bit is the source of the interrupt request.
6. Upon the completion of IRQ servicing, write a 0 into the NEWS bit to clear the NSIA bit and to negate IRQ if no other interrupt requests are pending.

DSP RAM Read Procedure

1. Reset MEMW to inform the DSP that a RAM read will occur when MEACC is set.
2. Load the RAM address code into the MEADDH and MEADDL registers.
3. Set MEACC to signal the DSP to perform the RAM read.
4. When the DSP has transferred the contents of RAM into the interface memory RAM data registers MEDAM and/or MEDAL, the MDP resets the MEACC bit and sets the NEWS bit to indicate DSP RAM read completion. If the NSIE bit is a 1, IRQ is asserted and NSIA is set to inform the host that setting of the NEWS bit is the source of the interrupt request.
5. Upon the completion of IRQ servicing, write a 0 into the NEWS bit to clear the NSIA bit and to negate IRQ if no other interrupt requests are pending.

4.3 RAM READ AND WRITE EXAMPLES

Figure 4-1 shows a flowchart of a procedure to change the DTMF tone duration using method 1.

Figure 4-2 shows a flowchart of a procedure to change the RTS-CTS delay using method 2.

Figure 4-3 shows a flowchart of a procedure to change the THRESHU value for TONEA using method 3.

Figure 4-4 shows a flowchart of a procedure to read EQM using method 4.

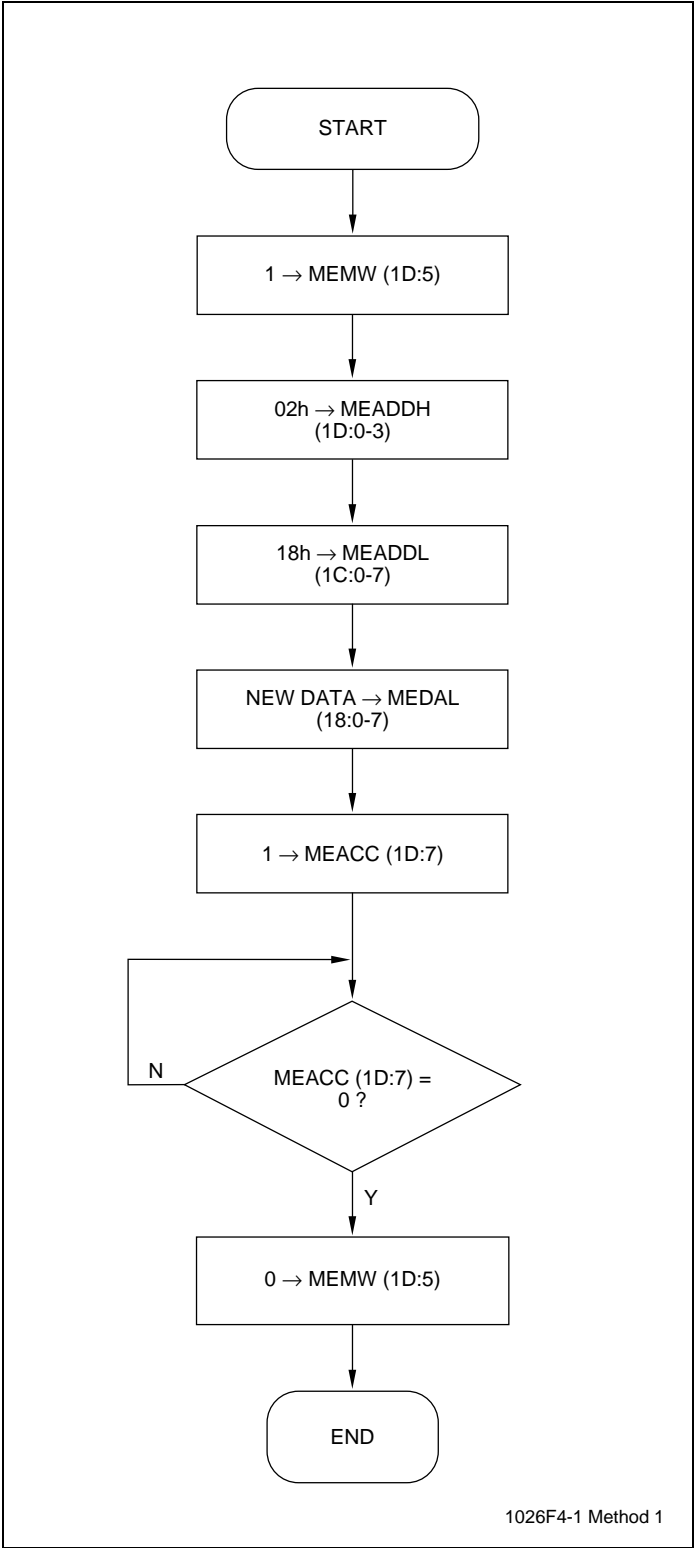

Figure 4-1. Method 1 Example - Changing DTMF Tone Duration (LSB)

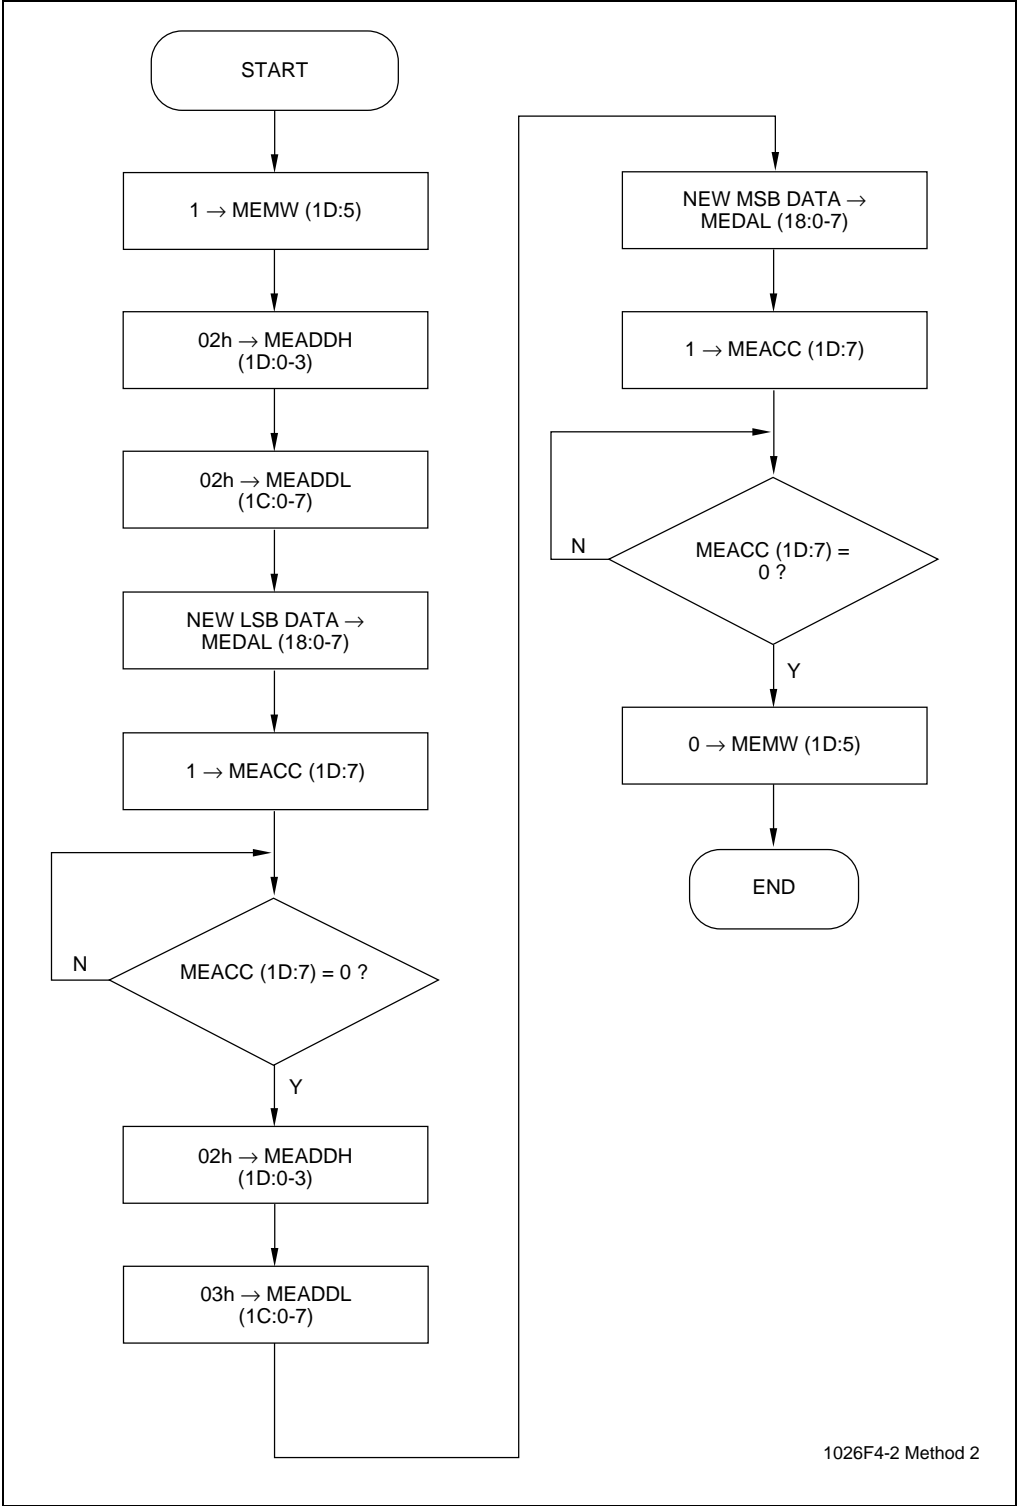

Figure 4-2. Method 2 Example - Changing RTS-CTS Delay

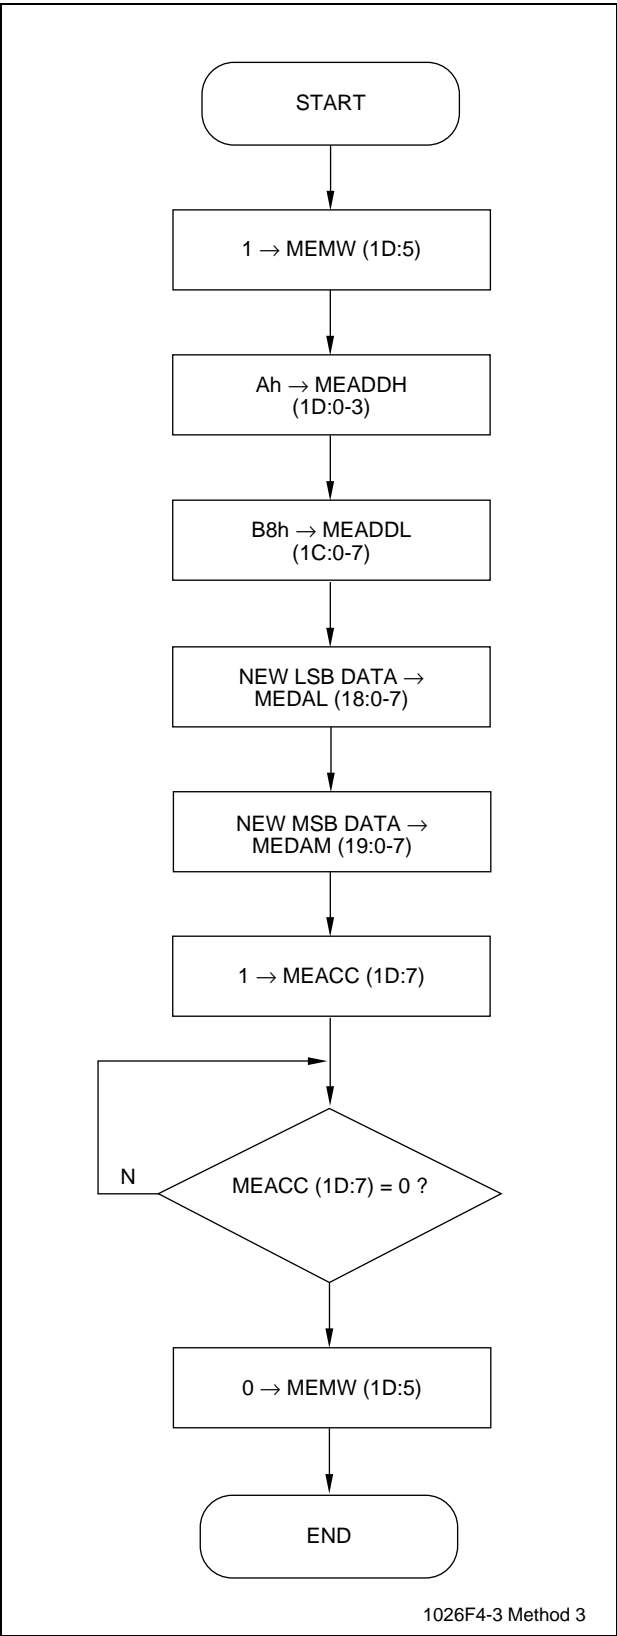

Figure 4-3. Method 3 Example - Changing TONEA THRESHU

Figure 4-4. Method 4 Example - Reading EQM

4.4 DSP RAM DATA SCALING

Function 1: **K56flex/V.34 Transmitter Speed** **Acc. Method: 1** **Addr.: 2E5h**
 K56flex/V.34 Receiver Speed **Acc. Method: 1** **Addr.: 2E4h**

When connected in K56flex or V.34, the current transmitter and receiver speeds may be read from 2E5h and 2E4h, respectively. These locations are updated after each handshake, retrain or rate renegotiation.

The speeds are reported as follows:

2E5h or 2E4h Value	K56flex/V.34 Transmitter Speed (2E5h) or V.34 Receiver Speed (2E4h) (kbps)	K56flex Receiver Speed (2E4h) (kbps)
0E	33.6	Reserved
0D	31.2	56
0C	28.8	54
0B	26.4	52
0A	24.0	50
09	21.6	48
08	19.2	46
07	16.8	44
06	14.4	42
05	12.0	40
04	9.6	38
03	7.2	36
02	4.8	34
01	2.4	32

Note: See Section 15 for V.90 rate information.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 2: V.32 bis and V.33 Rate Sequence

Acc Method: Table 4-1

Addr. 208h-2C9h

V.32 bis Rate Sequence Bits. ITU-T defines the V.32 bis rate sequence bits as follows:

BIT	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
DATA	0	0	0	0	1	X	X	1	1	X	X	1	X	0	0	1

B0 = MSB; B15 = LSB

Bit	Description
B0-B3, B7, B11, B15	For synchronizing on rate signal
B4	A 1 (Note 1)
B8	A 1 (Note 1)
B5	A 1 denotes the ability to receive at 4800 bps
B6	A 1 denotes the ability to receive at 9600 bps
B9	A 1 denotes the ability to receive at 7200 bps
B10	A 1 denotes the ability to receive at 12000 bps
B12	A 1 denotes the ability to receive at 14400 bps
B13, B14	0,0 (Note 2)
Notes	
1. When B4 or B8 is set to zero in a transmitted or received rate signal, then interworking can proceed only in accordance with Recommendation V.32.	
2. B13 and B14 shall be set to zero when transmitting and ignored during the reception of a rate signal; they are reserved for future definition by the ITU-T and must not be used by the manufacturers.	
3. B4-B6, B9-B10, B12 set to zero calls for a GSTN Cleardown.	

V.32 Rate Sequence Bits. ITU-T defines the V.32 rate sequence bits as follows:

BIT	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
DATA	0	0	0	0	1	X	X	1	1	X	X	1	X	0	0	1

B0 = MSB; B15 = LSB

Bit	Description
B0-B3, B7, B11, B15	For synchronizing on the rate sequence
B4	A 1 denotes the ability to receive at 2400 bps
B5	A 1 denotes the ability to receive at 4800 bps
B6	A 1 denotes the ability to receive at 9600 bps
B4-B6	0 0 0 calls for a GSTN clear down
B8	A 1 denotes the ability of trellis encoding and decoding at the highest data rate indicated in B3-B6.
B9-B14	0 0 1 0 0 0 denotes absence of special operational modes.
Note	
When using the MDP in a 7200 bps or 12000 bps proprietary configuration, B9 = 1 denotes the ability to receive at 7200 bps and B10 = 1 denotes the ability to receive at 12000 bps.	

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

V.33 Rate Sequence Bits. ITU-T defines the V.33 rate sequence bits as follows:

For B14 = 0:

BIT	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
DATA	0	0	0	0	X	X	X	1	X	X	X	1	X	X	0	1

B0 = MSB; B15 = LSB

Bit	Description
B0-B3, B7, B11, B15	For synchronizing on the rate sequence
B4-B6, B10, B12, B13	Not defined
B8	A 1 denotes the ability to receive at 12000 bps
B9	A 1 denotes the ability to receive at 14400 bps

For B14 = 1:

BIT	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
DATA	0	0	0	0	X	X	X	1	X	X	X	1	X	X	1	1

B0 = MSB; B15 = LSB

Bit	Description
B0-B3, B7, B11, B15	For synchronizing on the rate sequence
B4, B5	A 00 denotes that B6, B10, B12, and B13 define multiplexer configuration selection
B8	A 1 denotes the ability to transmit and receive at 12000 bps
B9	A 1 denotes the ability to transmit and receive at 14400 bps
B6, B10, B12, B13	Multiplexer configuration selection (see the V.33 specification for multiplexer configurations)

The V.32 and V.33 rate sequences contain undefined codes and/or bits. The user can use these bits to convey information to the remote modem during training (e.g., remote configuration, multiplexer configuration, test mode configuration, etc.).

The 16-bit rate sequence word in the MDP's RAM corresponds exactly to the 16-bit rate sequences defined in V.32 and V.33. The MSB of the word in RAM is B0 of the rate sequence and the LSB is B15 of the rate sequence.

V.32/V.32 bis Rate Sequence

The V.32/V.32 bis rate sequence is available in RAM during the handshake when the RSEQ bit is a 1. The RSEQ bit will turn on when the E-sequence is available as well. The rate sequence(s) and E-sequence are read from two different RAM locations (see Table 4-1 Function 2). The RSEQ bit must be reset by the host after reading the rate sequence(s).

The host may modify the rate sequence in one of two ways.

Method 1 Description. The first and simplest method is to use the rate sequence mask (see Table 4-1, Function 2). The rate sequence masks are available for R1, R2, R4, and R5. Rate sequences R1 and R2 are used during the initial handshake and retrains; R4 and R5 are used during rate renegotiations. The mask written to the appropriate RAM location will be logically ANDed to the out-going rate sequence. A power-on-reset will clear the masks to FFFFh.

Example of Method 1. To request or limit the MDP speed to 9600 bps, the host would write 0B91h (see page 4-8 for rate sequence bit assignments) to address 2C1h, 2C0h if R1 is to be modified. The same value could be written to address 2C5h, 2C4h if R4 is to be modified to limit the speed during a rate renegotiation. The available rates of the remote must be considered by the host before limiting speeds. If the MDP determines no common rate is available between both modems during a rate change, the MDP will send a clear down and turn off RLSD.

Method 2 Description. The second method for modifying the rate sequence is compatible with the RC144DP and is accomplished through address 205h, 204h. R1 and R3 are sent by the answering modem and R2 is sent by the originating modem.

To modify R1, the host must write a 0 at this address then wait for the value to equal non-zero. The host then has 1.5 seconds to change R1 (through address 205h, 204h) before it is sent.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

To modify R2, the host must wait until the RSEQ bit is set to a 1 by the DSP. The host then has 1.5 seconds to modify R2 (through address 205h, 204h).

To modify R3, the host must wait until the RSEQ bit is set to a 1 by the DSP, then change R3 (through address 205h, 204h).

In the case of rate renegotiations, R4 (sent by the requesting modem) is modified in the same manner as R3 after setting the RREN bit. R5 (sent by the responding modem) is also modified in the same manner after RREDT is set. The host has approximately 5 ms to modify R4 or R5 after the value in address 205h, 204h equals zero.

Typical rate sequences and E sequences shown in Table 4-2 (V32BS = 0) and Table 4-3 (V32BS = 1). The ARC bit is set on both modems. R1 and R3 are read on the originating modem, R2 is read on the answering modem. Refer to Section 5.3 of ITU-T Recommendation V.32/V.32 bis for additional information on the V.32/V.32 bis rate sequence.

Table 4-2. R and E Rate Sequences - V.32 to V.32 (V32BS = 0)

Originate Set at	R1 (Hex)	R2 (Hex)	R3 (Hex)	E (Hex) (ANS and ORG)	Answering Configuration	Resulting Configuration

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Functions 3-11: Dialing Parameters

Acc. Method: See Below

Addr.: See Below

For Functions 3, 4, 7, 8, and 9, the time T (in ms) is calculated as follows:

$$\begin{aligned} \text{Equation: } N &= T \times 2.4 && \text{Not in Speakerphone Mode} \\ N &= 1.76 && \text{In Speakerphone Mode (CONF = ACh)} \end{aligned}$$

Where: N is the decimal value of the hex number written to RAM (1-FFh).

A value of 0000 for the DTMF or calling tone on time will cause the MDP to transmit the tone continuously until FFh is written into TBUFFER.

For functions 10 and 11, the time (in ms) is calculated as follows:

$$\text{Equation: } N = T/10$$

For Functions 5 and 6, the DTMF low band or high band power level (P) in dBm is calculated as follows:

$$\text{Equation: } N = \log^{-1}(P/20) \times 10143$$

Where: N is the decimal value of the hex number written to RAM.

Notes:

1. The compromise equalizer is automatically disabled by the transmitter when sending DTMF tones, single tones, or dual tones. The DTMF levels are not affected by the transmit level bits (TLVL). The calling tones, however, are affected by the TLVL bits.
2. Maximum output power = -0.5 dBm.

The dialing parameters and their default values are:

Function	Parameter	Method	Address (Hex)	Default (Hex)	Default (Dec)
3	DTMF Tone Duration	1	2DB, 218	00DD	92 ms
4	DTMF Interdigit Delay	1	2DC, 219	00AD	72 ms
5	DTMF Low Band Power Level	2	29C, 29B	19C0	-4.0 dBm
6	DTMF High Band Power Level	2	29E, 29D	2085	-2.0 dBm
7	Pulse Relay Make Time	1	22C	56	36 ms
8	Pulse Relay Break Time	1	21C	99	64 ms
9	Pulse Interdigit Delay	2	21B, 21A	0708	750 ms
10	Calling Tone On Time	1	2D9, 290	0032	500 ms
11	Calling Tone Off Time	1	2DA, 291	012C	3 sec

Some DTMF power level values are:

L (dBm)	N (Hex)
-1	2350
-2	1F78
-3	1C0C
-4	1900
-5	1648
-6	13DB

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 12: Transmitter Output Level Gain-All Modes
Transmitter Output Level Gain-FSK Modes

Acc. Method: 2
Acc. Method: 3

Addr.: 3DBh, 3DAh
Addr.: B57h

Transmitter Output Level Gain-All Modes (Addr. 3DBh, 3DAh)

The transmitter output level gain constant (G) in dBm is calculated as follows:

$$\text{Equation: } N = \log^{-1} [G/20] \times 16384$$

Where: N is the decimal value of the hex number written to RAM.

Range: 0 - 7FFFh

Default: 4000h

NEWC must be set for the new gain value to take effect. The contents of 3DBh, 3DAh are copied to A48h (16 bits) which may also be used to directly control the transmit level.

The transmitter output level gain constant directly controls the output level of all configurations. It is used for fine tuning the output level which is controlled by the TLVL bits. Therefore,

$$\text{Output Level} = \text{TLVL Setting} + \text{Transmitter Output Gain in dBm}$$

Example gain values are:

G (dBm)	N (Hex)	G (dBm)	N (Hex)
+6	7FB2	-8	197A
+5	71CF	-9	16B5
+4	656E	-10	143D
+3	5A67	-11	1209
+2	5092	-12	1013
+1	47CF	-13	0E53
0	4000	-14	0CC5
-1	390A	-15	0B61
-2	32D6	-16	0A24
-3	2D4E	-17	090A
-4	2861	-18	080E
-5	23FD	-19	072E
-6	2013	-20	0666
-7	1C96	-21	05B4

For example, if TLVL is set for -9 dBm and the required level is -30 dBm, the difference is -21 dBm. Therefore, load addresses 3DBh and 3DAh with 05h and B4h, respectively, followed by setting NEWC.

The dynamic range of the scale factor is effective from +6 dB down to approximately -60 dB, with a resolution of 0.5E-3 dB.

Transmitter Output Level Gain-FSK Modes (Addr. B57h)

$$\text{Equation: } N = \log^{-1} [PO/20] \times C$$

Where: PO is based on TLVL = 9 and transmit output gain constant (all modes) and A48h = 4000h.

N is the decimal value of the hex number written to RAM.

C = See the following table:

Configuration	CEQ	C (Dec) - Answer	C (Dec) -Originate
V.21	CEQ = 1	9728	10608
	CEQ = 0	8448	8448
Bell 103	CEQ = 1	9072	10496
	CEQ = 0	8704	8352
V.23/1200 TX	CEQ = 1	12800	12800
	CEQ = 0	12544	12544
V.23/75 TX	CEQ = 1	10496	10496
	CEQ = 0	8448	8448

Setting NEWC to a 1 will reset this parameter to the default value.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 13: Dual Tone 1 Frequency

Acc. Method: 2

Addr.: 281h, 280h

Function 14: Dual Tone 2 Frequency

Acc. Method: 2

Addr.: 283h, 282h

Frequency F (in Hz) is calculated as follows:

$$\text{Equation: } N = F/0.109863$$

Where: N is the decimal value of the hex number written to RAM.

Default = 0

A single or dual tone is transmitted by writing 80h (single tone) or 83h (dual tone) to the CONF register, programming the tone transmit location in RAM, and then activating RTS. The tone will be transmitted as long as RTS is active.

Example values are:

F (Hz)	N (Hex)	F (Hz)	N (Hex)
400	0E39	2100	4AAB
445	0FD2	2250	5000
600	1555	2400	5555
1200	2AAB	3000	6AAB
1800	4000	3600	8000

Function 15: Dual Tone 1 Power Level

Acc. Method: 2

Addr.: 285h, 284h

Function 16: Dual Tone 2 Power Level

Acc. Method: 2

Addr.: 287h, 286h

Dual tone power level in dBm (PO) is calculated as follows:

$$\text{Equation: } N = 22304 [10^{PO/20}] \text{ (Based on TLVL = 0 and } 600 \Omega \text{ termination.)}$$

Where: N is the decimal value of the hex number written to RAM.

Range: 0 - 7FFFh (Default = 2000h)

Notes:

1. The MDP accepts change only when RTS is off.
2. The Transmit Level bits (TLVL) affect output level.
3. Power out = PO + TLVL setting + transmitter output gain constant.

Function 17A: New Status (NEWS) Masking Registers

Acc. Method: See Table 4-1 Addr.: See Below

Function 17B: Memory Access Masking Register

Acc. Method: 1 Addr.: 089h:6

Writing a 1 in the bit location corresponding to the desired bit will cause NEWS to go active when a status change occurs for the selected bit. All bits default to 0 at power-on-reset. Figure 4-5 shows the applicable masking register bits.

In addition, bit 089h:6 controls memory access interrupt (set 089h:6 to disable interrupt; reset 089h:6 to enable interrupt).

Register Address	Bit								Mask Address (Hex)
	7	6	5	4	3	2	1	0

Figure 4-5. NEWS Masking Registers

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 22: Far-End Echo Frequency Offset

Acc. Method: 4

Addr.: 852h

Function 22 provides the far-end echo frequency offset (FO), sometimes known as phase roll, in V.34/V.32 configurations.

Equation: $FO = (N * \text{SYMBOL RATE})/2^{22}$

Where: SYMBOL RATE = 2400, 2800, 3000, 3200, or 3429 (V.34) (See Function 60.)

2400 (V.32 bis)

N is the decimal value of the hex number read from RAM.

Function 22 is a 16-bit 2s complement number. It is not valid until rate sequence R3 is detected in the originate modem, or rate sequence R2 is detected in the answer modem for V.32 or until RLSD = 1 for V.34.

Function 23: Far-End Echo Level

Acc. Method: 4

Addr.: B52h

Function 23 provides the far-end echo power level at RXA in V.34/V.32 configurations.

The following table lists average values read from RAM and the corresponding far end echo level in dBm:

Echo Level (dBm)	V.34 Average Value (Hex)	V.32 bis Average Value (Hex)
-8	1100	1300
-9	0F00	1100
-10	0D00	0F00
-11	0C00	0D00
-12	0A00	0C00
-13	0900	0A00
-15	0700	0800
-20	0400	0500
-25	0250	0300
-30	0150	0180
-35	00C0	00D0
-40	0070	0080
-45	0045	0040

Note: Function 23 is not valid until RLSD is ON.

Function 24: CTS OFF-to-ON Response Time (RTS-CTS Delay)

Acc. Method: 2

Addr.: 203h, 202h

Function 24 determines the CTS off-to-on response time in 2-wire full-duplex configurations.

The response time equations and default values are:

Configuration	Equation	Default Value (Hex)	Default Value (Dec)
V.90, K56flex, V.34, V.32	$N = (\text{Response time} \times 2.4 \text{ ms}) - 1$	0000	0.4 ms
V.22 bis, V.22, Bell 212A	$N = (\text{Response time} \times 0.6 \text{ ms}) - 1$	0000	3 ms
Bell 103	$N = (\text{Response time} \times 0.298 \text{ ms}) - 1$	003F	215 ms
V.21	$N = (\text{Response time} \times 0.298 \text{ ms}) - 1$	0098	525 ms
V.23/1200Tx	$N = \text{Response time} \times 1.2 \text{ ms}$	00FC	210 ms
V.23/75Tx	$N = \text{Response time} \times 0.072 \text{ ms}$	0010	235 ms
Where: N is the decimal value of the hex number written to RAM.			

Example: For an RTS-CTS delay of 20 ms in V.22 bis, $N = [(20)(0.6)] - 1 = 11 = 000Bh$.

Notes:

- Response time may vary by ± 2 baud times.
- Function 24 is not applicable in V.33, V.17, V.29, V.27 and V.21 Ch 2.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 25: Answer Tone Length

Acc. Method: 2

Addr.: 229h, 228h

Function 26: Silence After Answer Tone Period

Acc. Method: 2

Addr.: 22Ah, 22Bh

The ITU-T 2100 Hz answer tone length and silence after answer tone are calculated as follows:

Configuration	Equation
V.8, V.32, V.21, Bell 103	$N = T \times 300$ (V.32 silence: $N = T \times 2400$)
V.22 bis, V.22, Bell 212	$N = T \times 600$
V.23/75Tx, V.23/1200Rx	$N = T \times 75$
V.23/1200Tx, V.23/75Rx	$N = T \times 1200$
Where: N is the decimal value of the hex number written to RAM and T is the time in seconds.	

The MDP will rewrite the default values when DTR is turned off or the NEWC bit is set.

The end of answer tone transmission may be determined by monitoring bit 051h:3. This bit will be set to a 1 when the answer has finished and the silence period has commenced. Unless a power-on reset is performed, this bit must be reset by the host if it is to be monitored again on the following connection.

Note: Address 229h, 228h lengthens individual phase reversal times in V.8/V.32 bis/V.32. The answer tone length may be adjusted by increasing or decreasing the number of phase reversals at address 04Bh. The default value at address 04Bh is 08h (8 phase reversals). This value may be changed only after DTR is set.

Functions 27 - 29: Tone Detector Bandpass Filter Coefficients

Acc. Method: 3

Addr.: See Table 4-4

A block diagram of the three tone detectors is shown in Figure 4-6. Tone detector C is preceded by a prefilter and a squarer. The purpose of the prefilter and squarer is to allow dual tones to be detected while rejecting the main channel energy. For example, TONEC can be programmed to detect a difference frequency generated by the squarer for detection of 350 Hz and 440 Hz. The prefilter would be designed to reject the energy in the 600 to 3000 Hz band. If the dual tone pair of 350 and 440 Hz appeared (or any other frequency pair in the range of 300 to 600 Hz with a difference of 90 Hz) TONEC would turn on.

The SQDIS bit (02h:6) allows the squarer in front of tone detector C to be disabled. If the squarer is disabled then tone detector C will have four cascaded biquads (since there is a prefilter consisting of two biquads), forming an 8-order IIR filter with user programmable coefficients. To make the prefilter transparent (to use TONEC as a 4th order filter), write 7FFFh in coefficients A1 and write 0000 to all other biquad coefficients.

The implementation of the filters allows user definition of the characteristics of the prefilter and the three tone detectors. Table 4-4 provides the DSP RAM address codes for the filter coefficients. Table 4-5 shows the default values. Figure 4-6 shows that the prefilter and the main filter sections of the tone detectors are fourth order (two second-order biquads in cascade), thereby allowing a wide variety of filter characteristics to be synthesized. The only limitation on these user-definable shapes is that their gain should be around unity at the pass frequencies to avoid problems of saturation at one extreme (gain too high) and digital noise at the other (gain too low). Computation of the filter coefficients can be performed by any infinite impulse response (IIR) filter design program which outputs the coefficients in cascaded second-order sections.

The default sample rate is 7200 Hz, however, in the V.8/V.34 mode, the sample rate is changed to 9600 Hz and all filter coefficients are changed by the MDP. A soft or hard reset is recommended after a V.34 connection to restore default filter coefficients.

The level detector in each of the tone detectors flags the detection of a tone if it is in the tone detector passband and if it is above an upper threshold defined by THRESHU. The tone detected flag will remain set until, or unless, the tone falls below a lower threshold defined by THRESHL.

The tone detectors are preceded by an AGC. The gain of the AGC may be read at address 8B9h (DUGAIN). By default, DUGAIN reaches its maximum gain, at a value of 7FFFh, when the receive level is -26 dBm or lower. Signal levels below -26 dBm are thus not affected by the AGC, therefore, the threshold comparator will see a decreasing signal level as the input signal is lowered. The THRESHU and THRESHL adjustments are limited to signal levels below the AGC cut-off point (-26 dBm). If the THRESHU value is adjusted to try to limit the detection threshold to -20 dBm, the AGC will not allow it.

To raise the AGC cut-off point, decrease the value in address BBB (DAGCRF). The DAGCRF default value is FF00h, which results in the -26 dBm cut-off. Decreasing DAGCRF to FE00h raises the AGC cut-off to -20 dBm, thus allowing THRESHU to be adjusted for a minimum detection level of -20 dBm or lower.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

The AGC may be disabled by first writing 0 to address 9BBh (DSRATE), then writing a 07FFh to address 8B9h (DUGAIN).

The first-order low pass filter in each level detector, defined by the coefficients LPGAIN and LPFBK, controls the response time of each tone detector. Normally, these coefficients will not require alteration, but if, for example, a rapid cadence must be detected on a tone, then the 3 dB cutoff is approximately the reciprocal of the on-time or off-time of the tone, whichever is shorter. Decreasing LPFBK will speed up the response time. If LPFBK is decremented, then LPGAIN should be increased by the same amount. The gain of the filter should be set to unity ($LPGAIN + LPFBK \cdot 7FFFh$). The default response time is in the order of 0.01 seconds.

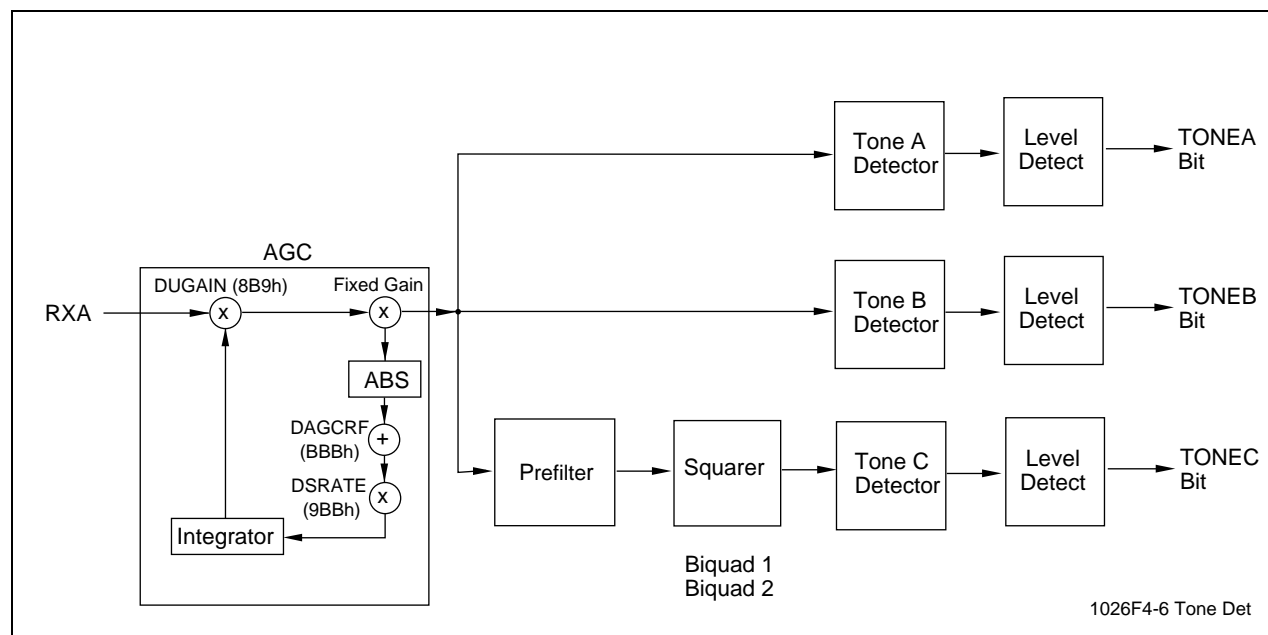

Figure 4-6. Tone Detectors

Table 4-4. TONEA, TONEB, and TONEC DSP RAM Addresses (Hex)

Parameter	TONEA		TONEB		TONEC		Prefilter

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Example:

A call-progress tone detector is required for the US telephone network to detect appropriate tones that exceed -35 dBm.

Solution:

The requirement can be met by detecting tones in the 245 Hz-650 Hz range. A bandpass filter with a passband of 245 Hz-650 Hz must be designed. Any filter up to fourth order can be implemented and, normally, it is best to choose the highest order available, especially for bandpass designs. A biquad filter design package could carry out this function by defining the passband frequencies, the filter order, the filter gain (chose unity), and the filter sampling rate (7200 Hz). An example of suitable coefficients is:

Function	A1	A2	A3	B1	B2
Biquad 1	0.1368	-0.2736	0.1368	1.8281	-0.8835
Biquad 2	0.1368	0.2736	0.1368	1.5716	-0.7920

These values should first be divided by two because coefficients greater than one are unrealized in the actual filter implementation. This division should be done even if none of the coefficients in the design are greater than one. This is because the biquad sections have been implemented as shown in Figure 4-7. The modified values are, therefore:

Function	A1'	A2'	A3'	B1'	B2'
Biquad 1	0.0684	-0.1368	0.0684	0.9140	-0.4418
Biquad 2	0.0684	0.1368	0.0684	0.7858	-0.3960

Next, convert the above numbers to fractional 2s complement numbers. In this case, the default coefficient values for TONEA:

Function	A1'	A2'	A3'	B1'	B2'
Biquad 1	08C2	EE7C	08C2	74FE	C774
Biquad 2	08C2	1184	08C2	6495	CD4F

The second part of the requirement is to detect tones that exceed -35 dBm. The approximate values of THRESHU and the corresponding tone level detected for TONEA at 500 Hz are:

THRESHU (Hex)	Tone Level Detected (dBm)
1100	-29
0C00	-32
0880	-35
0600	-38

THRESHU should be 0880h. If no hysteresis is required in the tone detector, then set THRESHL to 0880h (see Table 4-5). If hysteresis is required, then make THRESHL < THRESHU. Threshold levels stated in the data sheets are measured at the band edges. Other filter designs may require different values to those shown above. Note that changing threshold coefficients may change the bandwidth response of tone detectors.

Table 4-6 shows the filter coefficient values for specific filters. Adjust THRESHL and THRESHU as necessary (see Table 4-5).

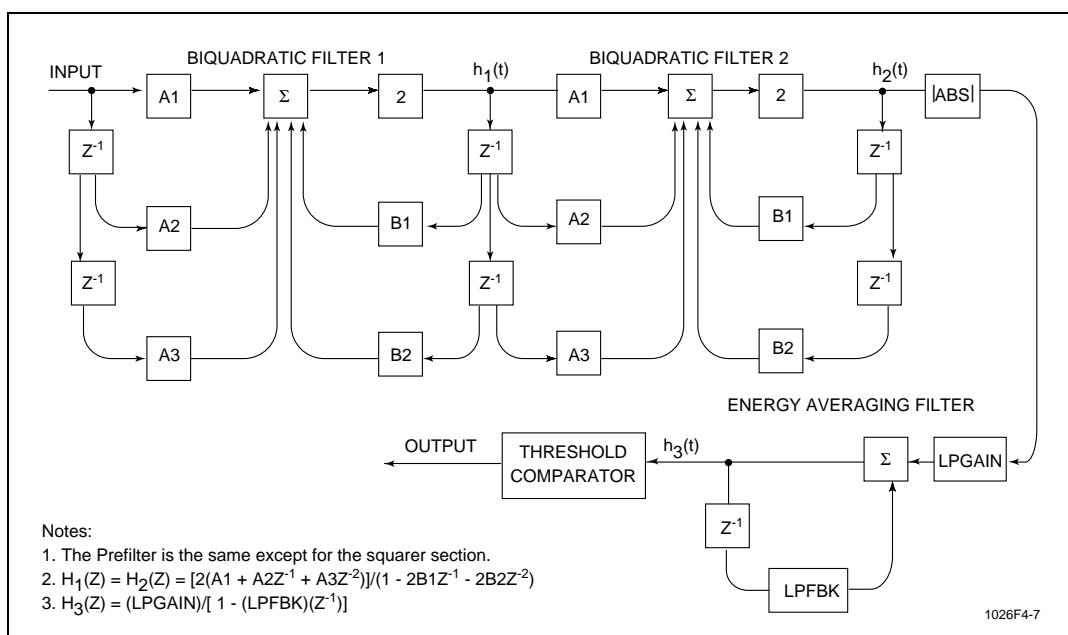

Figure 4-7. Biquad Filter and Level Detector

Table 4-6. Example Tone Detector Filter Coefficients

Sampling Rate/Filter	Biquad1 Coefficients (Hex)					Biquad2 Coefficients (Hex)

Notes: 1. TONEA default. 2. TONEB default.										

Function 30: RLSD Drop Out Timer

Acc. Method: 1

Addr.: 270h, 271h

V.32 bis, V.33, V.17, V.29, V.27, and V.21 channel 2

Address 270, 271 holds the value for a 16-bit counter which decrements at a baud interval when energy is removed from RXA. When the counter reaches 0000, RLSD turns off. The count down may be observed in addresses 389h (value from address 271h) and 388h (value from address 270h). The value in address 271h (MSB), 270h (LSB) may be changed anytime after RLSD = 1. The default time may be read in address 271h, 270h after RLSD = 1. See Table 1-2 for baud rates of individual modes. By prolonging the RLSD on-off time, the MDP can be kept in a freeze mode which can be used to bridge long dropouts. Dropouts of several seconds can be bridged by extending this timer. The default RLSD on-off time for V.32 bis is approximately 500 ms. Note that in V.32 bis mode, it is possible for the receiver to lock onto the local transmit signal when the received signal is lost. (See the DISDET description in Table 3-1.)

V.22 bis, V.22, Bell 212/1200

The 8-bit value in address 270h controls the RLSD on-off time. The value counts down to 0 in address 388h. Once this value starts to decrement, after the signal has been removed from RXA, the host may continuously write a large value in address 388, not allowing the counter to decrement, in order to prolong the RLSD on-off time if the 8-bit counter is not sufficient. This, however, requires the host to monitor address 388 during the connection until it starts to decrement.

The 8-bit value in address 271h controls the time the MDP will wait for energy to return after RLSD has turned off. This value is loaded into address 389h and starts to count up until it reaches a value of 63h. The default value in address 271h is 0 which gives the maximum freeze time of 63h bauds. After RLSD = 0, the host may continuously write 00 in address 389h, not allowing the counter to increment, in order to prolong the freeze time. Both addresses 271h and 270h may be written to after RLSD = 1.

Function 31: RLSD Turn-On Threshold (RLSD_ON)

Acc. Method: 2

Addr.: 135h, 134h

Function 32: RLSD Turn-Off Threshold (RLSD_OFF)

Acc. Method: 2

Addr.: 137h, 136h

RLSD Threshold Offset

Acc. Method: 2

Addr.: 139h, 138h

RLSD Overwrite Control

Acc. Method: 1

Addr.: 10Dh:2

Extended RTH Control

Acc. Method: 1

Addr.: 10Dh:6

A control bit (10Dh:2) enables or disables the over-writing of the RLSD thresholds by the MDP's own default threshold table [0 = overwriting enabled (default); 1 = overwriting disabled]. The default state is initialized only by power on or a soft reset.

The RLSD thresholds are loaded into memory locations RLSD_ON and RLSD_OFF. During the Idle mode initialization, the 2-byte value stored in RLSD_ON is used as the RLSD on threshold. When the MDP is in Data mode, the 2-byte RLSD_OFF value is used for the RLSD off threshold.

During reset, the respective thresholds for V.32 bis 14400 bps are loaded into RLSD_ON and RLSD_OFF as initial values. After reset, the host may then alter these values using the following procedure:

1. Set 10Dh:2 (to prevent custom values from being overwritten by default values).
2. Load in the custom RLSD values.
3. Set NEWC.

Note: the thresholds can be over-written at any time, but this method ensures that the first connection after a NEWC uses the correct value of ON threshold.

Extended RLSD Threshold Selection:

The Extended RTH bit (XRTH) (10Dh:6) controls the reduction of RLSD thresholds by approximately 5 dBm [0 = disables reduction (default); 1 = enables reduction]. If XRTH is a 1, RTH must be reset to 0. This extended RLSD threshold method affects all configurations while preserving the hysteresis.

The amount of threshold reduction (offset) can be controlled manually by the host writing a 16-bit offset value into address 139, 138. For example, this offset is useful for compensating for any loss or gain that may be introduced by the DAA/hybrid used. Note that if a negative offset is wanted, then the twos complement number should be entered. The maximum amount of offset that can safely be subtracted is 900h (F700h, 2s complement).

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 34: V.32 PN Length

Acc. Method: 2

Addr.: 289h, 288h

The V.32 bis/V.32 handshake and retrain sequence may be shortened or lengthened to meet special applications by adjusting the length of the PN (TRN) sequence. The answering modem sends two TRN sequences during the handshake while the originating modem sends only one.

The TRN time T (in ms) is calculated as follows:

$$\text{Equation: } N = (2.4 \times T) - 256$$

Where: N is the decimal equivalent of the hex number written to RAM and T is the time in ms.

Note: Values of N should be kept within 400h to 1F00h. A power-on reset will clear this location.

Changing the TRN lengths should be reserved for special applications only and is not recommended. Short TRN sequences may jeopardize the success of the handshake or retrain. Consult the ITU-T V.32/V.32 bis specifications for TRN length limitations. Only the originate TRN and the first answer TRN lengths are affected.

Function 36: AGC Gain Word

Acc. Method: 4

Addr.: A00h

Function 36 is useful for determining the receive level (RL) at TIP and RING. The number in RAM is related to the receive level as follows:

Configuration	Equation (AVAA = +5 V)	Equation (AVAA = +3.3 V)
V.90, K56flex, V.34, V.33, V.17, V.29, V.27	$RL = N/682.7 - 52 \text{ dB}$	$RL = N/682.7 - 56 \text{ dB}$
V.32 bis, V.32	$RL = N/682.7 - 53 \text{ dB}$	$RL = N/682.7 - 57 \text{ dB}$
V.22 bis, V.22, Bell 212, V.23/1200	$RL = N/682.7 - 48 \text{ dB}$	$RL = N/682.7 - 52 \text{ dB}$
V.21, V.23/75	$RL = N/682.7 - 54 \text{ dB}$	$RL = N/682.7 - 58 \text{ dB}$
Bell 103	$RL = N/682.7 - 51 \text{ dB}$	$RL = N/682.7 - 55 \text{ dB}$
Where: N is the decimal value of the hex number read from RAM.		
Note: Formulas are valid only if the receive level is above the RLSD off-to-on threshold.		

Note: V.90 and K56flex modes use an auto gain stage in the receive path, prior to the AGC calculation. The amount of auto gain can be read after phase 2 from bits 2 and 1 of address 3CBh and bit 4 of address 3CDh. Bits 2 and 1 of address 3CBh = 0, 10, 15, and 20 dB of gain, corresponding to bit values of 00, 01, 10, and 11, respectively. Bit 4 of address 3CDh, when set, corresponds to -4 dB of attenuation. Both gain and attenuation settings may result. To obtain the true receive level at TIP and RING, subtract the total gain from addresses 3CBh and 3CDh from the calculated AGC level.

Function 37: Round Trip Far Echo Delay

Acc. Method: 4

Addr.: 239h

Function 37 provides the value of the round trip delay measured during the handshake.

$$\text{Equation: } RTD = (N/X) - 3.5 \text{ (for V.34)}$$

$$RTD = (N/2.4) - 29 \text{ (for V.32 bis)}$$

Where: RTD = Round Trip Delay in ms

N = Decimal equivalent of value read from RAM

X = symbol rate/1000, i.e., 2.4, 2.8, 3.0, 3.2, or 3.429 (see Function 60).

Function 45: Equalizer Frequency Correction

Acc. Method: 4

Addr.: 811h

Function 45 provides the value of the Equalizer Frequency Correction (V.32 bis only).

$$\text{Equation: } F = N/27.3 \text{ (for V.32 bis)}$$

Where: F = Carrier frequency offset in Hz

N is the decimal value of the hexadecimal number read from RAM

Function 46: Eye Quality Monitor

Acc. Method: 4

Addr.: 20Ch

Note: See Sections 14 and 15 for EQM readings in K56flex and V.90 modes, respectively.

In V.32 4800 bps, V.29, V.27, V.22 bis, V.22 and Bell 212A modes, EQM is the filtered squared magnitude of the error vector. However, for all TCM modes (V.34, and V.33 modes, and V.32 12000, 9600, and 7200 bps modes), EQM is the filtered minimum trellis path length (or metric). This gives a better indication of signal quality for trellis modes.

The error vector formed by the decision logic can be used to indicate relative signal quality. As signal quality deteriorates, the average error vector increases in magnitude. By calculating the magnitude of the error vector and filter the results, a number inversely proportional to signal quality is derived. This number is called the eye quality monitor (EQM). Because of the filter time constant, EQM should be allowed to stabilize for approximately 700 baud times following RLSD going active.

The EQM value for the non-trellis configurations is the filtered squared magnitude of the error vector and represents the average signal power contained in the error component. The power is directly proportional to the probability of errors occurring in the received data and can be used to implement a discrete Data Signal Quality Detector circuit (circuit 110 of ITU-T Recommendation V.24 or circuit CG of the RS-232-C standard) by comparing the EQM value against experimentally determined criteria (Bit Error Rate curves).

Figure 4-8 illustrates the relationship of the EQM number to an eye pattern created by a 4-point signal structure (e.g., V.29/4800 bps) in the presence of high level white noise. The EQM value is proportional to the square of the radius of the disk around any ideal point. The radius increases when signal to noise ratio (SNR) decreases. As the radius approaches the ideal point's boundary values, the bit error rate (BER) increases.

Curves of BER as a function of the SNR are used to establish a criteria for determining the acceptability of EQM values. Therefore, from an EQM value, the host processor can determine an approximate BER value. If the BER is found to be unacceptable, the host may cause the MDP to fallback to a lower speed to improve BER.

It should be noted that the meaning of EQM varies with the type of line disturbance present on the line and with the various configurations. A given magnitude of EQM in V.29/9600 does not represent the same BER as in V.27/4800. The former configuration has 16 points that are more closely spaced than the four signal points in the latter, resulting in a greater probability of error for a given level of noise or jitter. Also, the type of line disturbance has a significant bearing on the EQM value. For example, white noise produces an evenly distributed smearing of the eye pattern with about equal magnitude and phase error while phase jitter produces phase error with little error in magnitude.

Since EQM is dependent upon the signal structure of the modulation being used and the type of line disturbance, EQM must therefore be determined empirically in each application.

Figure 4-8. Relationship of EQM to Eye Pattern

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 47: Maximum Period of Valid Ring Signal

Acc. Method: 1

Addr.: 21Fh

Function 48: Minimum Period of Valid Ring Signal

Acc. Method: 1

Addr.: 21Eh

The ring detector measures the period of pulses on the ring detect input and determines whether the pulses are within the frequency range specified by the Maximum Period of Valid Ring Signal and Minimum Period of Valid Ring Signal functions. Since maximum period corresponds to minimum frequency, the formula for calculating these functions is given in terms of frequency.

Frequency F (in Hz) is calculated as follows:

Equation: $N = 2400/F$

Where: N is the decimal value of the hex number written to RAM (05h-FFh).

Default: The default values are:

Function	Parameter	Method	Address	Default (Hex)	Default (Dec)
47	Maximum Period of Valid Ring Signal	1	21Fh	A0	15 Hz
48	Minimum Period of Valid Ring Signal	1	21Eh	23	68 Hz

Note: Writing 00 to Function 48 will cause the RI bit state and ~RI output pin level to follow the RINGD input pin level.

Function 49: Phase Jitter Frequency

Acc. Method: 4

Addr.: 80Eh

The phase jitter frequency estimate is available in V.34/V.32 bis/V.32 mode only. The phase jitter amplitude must be greater than approximately 6 degrees with a minimum frequency of 10 Hz in order for the MDP to lock on and track the jitter.

Equation: $F = N \cdot \text{Symbol Rate} / 2^{16}$ (V.34)

$F = N / 27.3$ (V.32 bis/V.32)

Where: F is the frequency in Hz.

N is the decimal equivalent of the hex number read from RAM.

Symbol Rate = 2400, 2800, 3000, 3200, or 3429.

Function 50: Phase Jitter Amplitude

Acc. Method: 4

Addr.: 80Dh

The phase jitter amplitude estimate is available in V.34/V.32 bis/V.32 mode only. The phase jitter amplitude must be greater than approximately 6 degrees with a minimum frequency of 10 Hz in order for the MDP to lock on and track the jitter.

Equation: $AP = N / 90$

Where: AP is the amplitude in degrees.

N is the decimal equivalent (absolute value) of the hex number read from RAM

Function 51: Guard Tone Level

Acc. Method: 3

Addr.: B46h

Guard tone power in dBm (PO) is calculated as follows (based on TLVL bits = 9 and 600 Ω termination):

Configuration	Equation	Default Value (Hex)
1800 Hz guard tone (GTS bit = 0; CEQ bit = 1)	$N = 4926 [10^{PO/20}]$	036C
1800 Hz guard tone (GTS bit = 0; CEQ bit = 0)	$N = 8458 [10^{PO/20}]$	05E0
550 Hz guard tone (GTS bit = 1; CEQ bit = 1)	$N = 5128 [10^{PO/20}]$	0390
550 Hz guard tone (GTS bit = 1; CEQ bit = 0)	$N = 8458 [10^{PO/20}]$	05D8

Notes:

1. Setting the NEWC bit will reset the power level to its default level.
2. The power level may be adjusted only after the GTE bit is set.
3. The transmit level bits (TLVL) affect the guard tone power output level.
4. Guard tone power is available in V.22 bis/2400 or V.22/1200 answer mode only.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 52: ITU-T CRC 32 Select

Acc. Method: 1

Addr.: 0B3h(0)

The type of cyclic redundancy check (CRC) generation and detection can be selected by writing to bit 0B3h:0 [0 = ITU-T CRC 32; 1 = ITU-T CRC 16 (default)].

Function 53: Secondary Channel Transmitter Speed Select (V.32 bis/V.32)

Acc. Method: 1

Addr.: 28Eh

Secondary Channel Receiver Speed Select (V.32 bis/V.32)

Acc. Method: 1

Addr.: 28Bh

The default data rate for the secondary channel is 150 bps. The rate can be changed by modifying a divide factor in two addresses: 28Eh for the transmitter and 28Bh for the receiver. The following table lists the possible secondary channel speeds for the various main channel speeds and the corresponding RAM value. Reset will clear locations 28Eh and 28Bh.

Main Channel Speed (bps)	Secondary Channel Speed (bps)					
	Transmitter and Receiver RAM Divide Constant Values (Hex)					
	75	150	300	600	1200	2400
14400	8	10				
12000	8	10				
9600 TCM	4	8	10			
9600 QAM	2	4	8	10		
7200	2	4	8	10		

Functions 54 - 59: Not Applicable.

Function 60: V.34 Symbol Rate Value

Acc. Method: 1 (RO)

Addr.: 2E3h

Function 61: V.34 Baud Rate Mask (BRM)

Acc. Method: 1

Addr.: 101h

During the start-up handshake, the MDP probes the communication channel and determines the available bandwidth. This information helps establish the common symbol rate between the modems. The following data rate ranges are available for a selected symbol rate:

Symbol Rate (baud)	Highest Possible V.34 Data Rate (bps)
2400	21600
2800	26400
3000	28800
3200	31200
3429	33600

If line conditions cannot support the higher symbol rates, the MDP automatically reduces the data rate to match the allowable symbol rate.

The host can control the symbol rate negotiation process via the Baud Mask Register (BMR), located at address 101h. By either setting or resetting one or more of five bits in the BMR, the host can specify if a particular symbol rate is to be supported. In Loop 3 (L3ACT = 1), the baud rate may be selected by writing the desired symbol rate value (0, 2, 3, 4, or 5) to address 2E3h anytime prior to establishing the loopback. The default value is 4 for 3200 baud. The symbol rates and the corresponding bit positions are:

Symbol Rate (baud)	Symbol Rate Value (Addr. 2E3h)	Baud Mask Register (BRM) Enable Bit Position (Addr. 101h)
2400	0	0
Reserved	1	1*
2800	2	2
3000	3	3
3200	4	4**
3429	5	5
* Bit 1 must always be a 1.		
** Bit 4 (3200 symbol rate) must be set for V.90/K56flex operation.		

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

When the MDP determines, from the bandwidth, the maximum supportable symbol rate, the MDP will enable all symbol rates below that maximum value. For example, if the line probe indicates that the bandwidth is adequate to support 3000 baud, then 2800 and 2400 baud will also be supported. This selection of symbol rates is, however, dependent upon the contents of the BMR. Again, for the same example, if a host does not want to support 2800 baud, the host must reset bit 2 of the BMR. If both modems do not agree during probing, e.g., the originate modem chooses 3000 baud and the answer modem chooses 2800 baud, then the highest common rate will be 2400 baud. In the event there is no common rate, the modems will default to 2400 baud.

Figure 4-9 shows the symbol rate negotiation process. The final symbol rate chosen may be read from address 2E3h after the negotiation is complete. A value of 10h, for example, would indicate a symbol rate of 3200 baud.

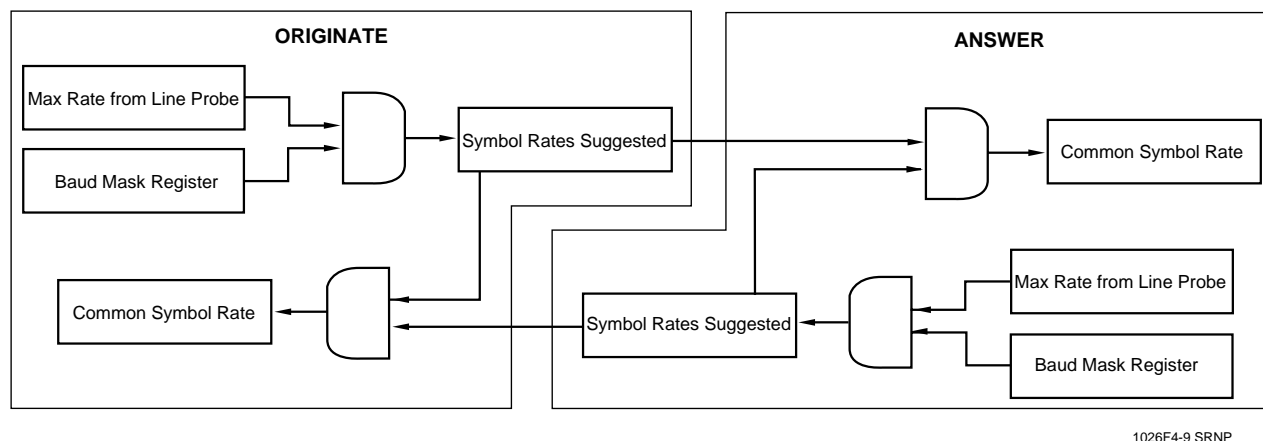

Figure 4-9. V.34 Symbol Rate Negotiation Process

Function 62:	V.34 Pre-Emphasis Filter Number	Acc. Method: 4	Addr.: B44h
Function 63:	V.34 Pre-Emphasis Filter Override Number	Acc. Method: 1	Addr.: 0E6h
	V.34 Emphasis Disable	Acc. Method: 1	Addr.: 100h:1

There are 11 pre-emphasis filters defined, each matching the templates defined in ITU-T V.34.

The Pre-emphasis filter selected can be read from the V.34 Pre-Emphasis Filter Number (address B44h).

The Pre-emphasis negotiation can be ignored by setting bit 100h:1, Pre-emphasis Disable (PREDIS). This bit does not stop the measurement or the transmission of the suggested pre-emphasis filter, but rather causes the receiver to ignore the suggestion.

Pre-emphasis can also be controlled by using the CEQ bit in the MDP interface memory. If this bit is reset, any selected pre-emphasis or transmit compromise filter will be ignored. In this way, the host can control pre-emphasis by setting/resetting CEQ. However, if the host wishes to use a custom compromise filter, then by using the PREDIS bit, the suggested filter will be ignored and the host's custom defined compromise filter will be used.

The procedure to manually select one of the pre-emphasis filters is:

1. Set the PREDIS bit (100h:1) to override negotiation.
2. Load the Pre-Emphasis Filter Over-Ride Number (address 0E6h) with the Pre-emphasis Filter Suggestion Number from the table above.
3. Ensure that CEQ is on.

Function 64:	V.34 Transmit Level Deviation Disable	Acc. Method: 1	Addr.: 100h:3
---------------------	--	-----------------------	----------------------

During line probing, the MDP measures the receive level of the line signal. If that receive level is high enough, the MDP suggests that the remote modem reduce its own transmit level in order to improve signal-dependent noise performance.

The transmit level power drop does not use receive level alone. Decision is also based on noise and harmonic distortion criteria.

To force the MDP to ignore the suggested transmit level reduction, set the Transmit Level Deviation Disable (TLDDIS) bit (100h:3) to a 1.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 65-67: Not Applicable

Function 68: EQM Above Threshold

Acc. Method: 1

Addr.: 133h

When the high byte of the EQM reading (address 20Dh) goes above the EQM Above Threshold, the MDP will assert the EQMAT bit (0Bh:1). The host can set up a NEWS interrupt to monitor changes to this bit (see EQMAT in Function 17). The default value of EQM Above Threshold is 30h and is written at POR and is unaffected by NEWC. The MDP does NOT reset the EQMAT bit; the host must reset the EQMAT bit.

Function 69: ARA-in RAM Enable EQM Scale Factor (Gain)

Acc. Method: 1

Addr.: 3A5h:4

Acc. Method: 3

Addr.: A29h

The automatic rate adaptation (ARA) algorithm adjusts the data rate based on the level of EQM. The ARA is recommended with the initial train and retrain only. Rate-renegotiation should be performed with ARA off, allowing the host to decide the optimal data rate based on EQM readings. ARA is enabled by setting the EARC bit (15h:0), which defaults off.

Upon initial train and retrain, the EQM is checked during the training, just before the rate negotiation. The 4-point EQM is compared against a table of values representing the necessary levels to achieve the corresponding V.34/V.32 bis data rates with an EQM of around 2000h. Once the maximum achievable rate is determined, the CONF register is changed to reflect the estimate, and is then used to suggest a data rate in the following negotiations.

Modifying the ARA Thresholds in RAM (V.34 Mode only)

The 'ARA-in-RAM' function is enabled by setting bit 3A5h:4 (8-bit access).

Sixteen RAM locations are allocated for the ARA-in-RAM thresholds. These occupy locations 3B0h to 3BFh.

The Search table used for determining the best data rate for a given EQM is uniquely organized. The search through the table starts at the low address first, which represents the lowest data rate*, and progresses through to the higher data rates as the measured EQM value during training decreases. The final measured EQM is compared to the ARA RAM table. The EQM value must be greater than the threshold value in RAM for the corresponding data rate to be selected. For example, in the table below, if the final measured EQM were between 0028 and 0090, the data rate of 26.4k would be selected. If the EQM value were less than 0028, the data rate of 28.8k would be selected. As another example, to allow more aggressive 28.8k connections, the threshold under the 26.4k rate (0028) should be increased. This would require the measured EQM to be slightly worse before falling back to 26.4k.

At the low data rates only the most significant byte of EQM is used in the threshold testing. However, as the thresholds get smaller for the higher data rates, it is necessary to use the least significant byte of EQM for the required resolution. When this transition occurs, the table of thresholds must contain a 0, followed by the appropriate low byte threshold value. The last location to be searched must contain a 0 to stop further searches.

* Normally for symbol rates above 2400 baud, the starting point is at address 3B1h and the initial data rate is 4800 bps. For the case of 2400 baud, the starting point is at 3B0h and the initial data rate is 2400 bps.

The following table of default thresholds against data rates is used in the ARA-in-RAM function.

Data Rate (kbps)	2.4	4.8	7.2	9.6	12.0	14.4	16.8	19.2	21.6	24.0	26.4	28.8	31.2	33.6
Threshold (Hex)	2000	1A00	1200	0C00	0A00	0900	0500	0300	0200	0090	0028	0010	0004	0001

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Consequently, the default values written into RAM are:

Address (Hex)	Value (Hex)	Comment
3B0	20	
3B1	1A	
3B2	12	
3B3	0C	
3B4	0A	
3B5	09	
3B6	05	
3B7	03	
3B8	02	
3B9	00	Note: This 0 causes the search algorithm to use low byte of EQM
3BA	90	The next threshold (it is equal to 00E0h)
3BB	28	
3BC	10	
3BD	04	
3BE	01	
3BF	00	

Configuring the ARAinRAM Thresholds During the V.34 Handshake

The thresholds are designed for optimum connectivity at symbol rates of 3429 and 3200. Whereas this will cover the vast majority of connections, the user may wish to alter the ARA-in-RAM values when symbol rates of 3000 and below are required. In this situation, the host can read the symbol rate and then load a new set of ARA-in-RAM values into the address range specified. This is to be done at the start of Phase 3 of the handshake.

Method:

1. Monitor the Receive Handshake Status (16h, SECRXB). Wait until it is set to 4X.
2. Read the selected connection symbol rate (address 2E3h, Function No. 60).
3. Write in appropriate ARAinRAM thresholds for that symbol rate in addresses 3B0h through to 3BFh, using the information provided above. (8-bit access).

Forced 2400 Symbol Rate when Probing SNR is Adverse

If the signal-to-noise ratio (SNR) is less than the specified threshold, the data pump overrides the bandwidth evaluation algorithm and forces the Symbol Rate to 2400 baud. This allows the MDP to fallback to 2400 bps if the SNR is poor as defined by this threshold. The threshold is located in RAM at address 3C0 and the bit which enables this feature is bit 3A5:5. The default for this bit is enabled and the default threshold value is 0Dh which approximates to a SNR of 12 dB. All RAM accesses are 8-bit.

Modifying the EQM Gain

A simpler, but less attractive, method to affect these rate adjustments is to increase the EQM gain at address A29h for a more reliable connection or to lower the EQM gain for a less reliable connection. The default value is 1000h. This method affects the EQM reading at address 20Ch.

In V.34, the EQM gain may be changed after the SDET bit is set.

In V.32 bis, the EQM gain may be changed after the DTR bit is set.

Example 1: If a more reliable (lower speed) connection is desired, increase the EQM gain from the normal value of 1000h to 2000h. The rate selected would then be one lower, e.g., 21600 will be selected whereas 24000 would have been selected without the change.

Example 2: If a less reliable (higher speed) connection is desired, decrease the EQM gain from 1000h to 0800h.

See Section 14.1.7 for manual ARA adjustments in K56flex and V.34 modes.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 70: V.21/V.23 CTS Mark Qualify

Acc Method: 1

Address: 10Dh:3

In V.21/V.23 configurations, CTS turn-on qualifying time can be controlled by writing to bit 10Dh:3 [0 = no qualifying time after Mark (default); 1 = qualifying time of 45 ±5 ms after Mark]. This bit is unaffected by the action of NEWC.

Function 71-72: Not Applicable

Function 73: No Automode to FSK

Acc Method: 1

Address: 13Fh:0

Automode to FSK modes can be controlled by writing to bit 13Fh:0 [0 = automode to FSK enabled (default); 1 = automode to FSK disabled]. This bit remains unaffected by NEWC.

If enabled (0), the automode selection will allow FSK connections. If disabled (1), automode selection will not configure to any FSK mode.

Function 74: Receive FIFO Trigger Level Transmit FIFO Extension Enable Receive FIFO Extension Enable

Acc Method: 1

Address: 32Ch

Acc Method: 1

Address: 702h:0

Acc Method: 1

Address: 701h:0

Transmitter FIFO (TXFIFO)

The 16-byte TXFIFO is controlled by writing to the FIFOEN bit (04h:4) [0 = TXFIFO disabled; 1 = TXFIFO enabled].

The 128-byte TXFIFO Extension (TXFIFOX) is controlled by writing to the Transmit FIFO Extension Enable bit (702h:0) [0 = TXFIFOX disabled; 1 = TXFIFOX enabled (default)].

When the TXFIFO is enabled (FIFOEN = 1), the host can continuously write to TBUFFER as long as TXFNF status bit (0Dh:1) is set. The TDBE bit (1Eh:3) will be set whenever the TXFIFO is empty (TXFIFOX disabled) or when the TXFIFO can accept more bytes (TXFIFOX enabled). Two control bits, TEOF (11h:1) and TXP (11h:0) are buffered along with the TXFIFO data. The TEOF bit is used in HDLC mode to indicate that the next byte written into TBUFFER is the last byte of the frame. TXP is used in 8-bit, stuff parity asynchronous mode to indicate the parity bit. Also, the TXHF status bit (01h:2) indicates when the TXFIFO is half full.

When the TXFIFO is disabled (FIFOEN = 0), the TXFIFO is one byte in length.

When disabling the FIFO extensions (702h:0 = 0 or 701h:0 = 0), the host must wait until connected in data mode (RLSD = 1) before doing so. If a retrain or rate renegotiation occurs, bits 702h:0 and 701h:0 must again be cleared after completion of the retrain or rate renegotiation (CTS = 1) if disabling the FIFO extensions is desired.

To stop transmission of data presently in the Transmit FIFO, clear bit 702h:0 and reset bit FIFOEN to 0.

Receiver FIFO (RXFIFO)

The 16-byte RXFIFO is always enabled.

The 128-byte RXFIFO Extension (RXFIFOX) is controlled by writing to the Receive FIFO Extension Enable bit (701h:0) [0 = RXFIFOX disabled; 1 = RXFIFOX enabled (default)].

The lower 16-byte portion of the RXFIFO can be controlled by writing to address 32C. The default value is CBh which gives a trigger level of 14 bytes and a time-out of 17 clock cycles.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Bits 7-6 Trigger Level. Selects the trigger level in the 16-byte RXFIFO. For example, setting bits 7 and 6 to 1 selects a trigger level of 14 bytes. That is, RDBF will not become asserted until the receive FIFO is 14 bytes full and the time-out delay has not elapsed (see below). Both RDBF and RXFNE will remain set until the RXFIFO is empty.

Bit 7	Bit 6	Trigger Level (No. of Bytes)
0	0	Trigger level = 1
0	1	Trigger level = 4
1	0	Trigger level = 8
1	1	Trigger level = 14

Bit 5 Must be 0.

Bits 4-2 Time-out Delay. Selects the length of idle time that will cause RDBF to be asserted when the RXFIFO is not empty. Idle time is the length of time that elapses without the MDP writing into the RXFIFO or the host reading data from the RXFIFO. This feature prevents data from being "held up" in the RXFIFO.

B4	B3	B2	Idle Time (In Bit Times)
0	0	0	9 bit times
0	0	1	13 bit times
0	1	0	17 bit times
0	1	1	21 bit times
1	0	0	25 bit times
1	0	1	29 bit times
1	1	0	33 bit times
1	1	1	37 bit times

Bit 1 Idle Time Time-out Enable. 1 = the time-out enabled; 0 = time out disabled. When Time out is disabled (0), RDBF will be asserted only when the RXFIFO threshold is reached.

Bit 0 Not Used.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

RXFIFO Error Status Bits

The RXFIFO includes five error status bits: BRKD (0Eh:6), SYNCD (0Ah:1), RXP (01h:0), FE (0Ah:4), and PE (0Ah:5). SYNCD is used for 7E flag detection in HDLC mode only and BRKD indicates that an asynchronous break has been received. FE indicates a framing error in asynchronous mode or an abort condition in HDLC mode. PE indicates an asynchronous parity error or a CRC error in HDLC mode. RXP indicates the received parity bit in 8-bit asynchronous stuff parity mode.

IMPORTANT: The host must read the status bits prior to reading the byte from RBUFFER. Note that this is the opposite of how it should be done using the RC96DPL/RC144DPL or RC96DPi/RC144DPi.)

Also, there are two status bits (RXHF and RXFNE) that the host can use to monitor the RXFIFO operation. RXHF (01h:1) indicates when the receive FIFO is half full and RXFNE (0Ch:1) is set whenever RXFIFO contains data.

Function 75-80: Not Applicable

Function 81: V.34 Spectral Parameters Control

Acc Method: 1

Address: 105h

The host can control some of the spectral parameters that the transmitter uses for cases where the local PTT has regulations governing transmission. These control bits should be used in their default state and the host need only alter them if required to meet PTT approval.

- Bit 7** **Transmitter Enable for the Low Carrier Frequency for 3200 Baud.** When set, the transmitter can use the low carrier frequency for 3200 baud.
- Bit 6** **Transmitter Enable for the High Carrier Frequency for 3200 Baud.** When set, the transmitter can use the high carrier frequency for 3200 baud.
- Bit 5** **Transmitter Enable for the Low Carrier Frequency for 3000 Baud.** When set, the can use the low carrier frequency for 3000 baud.
- Bit 4** **Transmitter Enable for the High Carrier Frequency for 3000 Baud.** When set, the can use the high carrier frequency for 3000 baud.

Bits 3:0 **Reserved.** Do not alter the contents.

Function 82: V.34 Phase 2 Power Reduction

Acc Method: 1 (RO)

Address: 0E2h

In V.34 mode, the MDP supports the reduction in transmit power if instructed by the remote modem during the start-up sequence. The amount of power drop from the nominal is 0 to 14 dB. The TLDDIS bit (100h:3, see Function 64) enables the local modem to implement the amount of power drop being suggested by the remote modem or to ignore it and not drop the level at all. Function 82 specifies the amount of power drop in dB after Phase 2.

Function 83-84: Not Applicable

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 85: V.34 Data Rate Mask **Acc Method: 2** **Address: 383h, 382h**
K56flex/V.34 Transmitter Maximum Data Rate Mask **Acc Method: 1** **Address: 605h**
K56flex/V.34 Receiver Maximum Data Rate Mask **Acc Method: 1** **Address: 604h**

Note: See Section 15 for V.90 Rate Mask description.

The V.34 data rate masks occupy two bytes in RAM. Locations 382h and 383h represent the lower byte and the upper byte of the mask, respectively (Table 4-7). The bits in the mask represent the enabling of a particular data rate if set or disabled if reset. The definition of the bits are data rate 2400 is at bit 0 (i.e., the LSB of address 382h), 4800 is at bit 1, 7200 at bit 2 and so on up to 33600 bps (in 2400 bps increments) which is bit 13 of the mask (or bit 5 of address 383h. Bits 14-15 are reserved.

Table 4-7. V.34 Rate Sequence Mask Bit Assignments

Data Rate (bps)	V.34 Data Rate Mask-MSB (Address 383h)								V.34 Data Rate Mask-LSB (Address 382h)							
	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0
2400	-	-	X	X	X	X	X	X	X	X	X	X	X	X	X	1
4800	-	-	X	X	X	X	X	X	X	X	X	X	X	X	1	X
7200	-	-	X	X	X	X	X	X	X	X	X	X	X	1	X	X
9600	-	-	X	X	X	X	X	X	X	X	X	X	1	X	X	X
12000	-	-	X	X	X	X	X	X	X	X	X	1	X	X	X	X
14400	-	-	X	X	X	X	X	X	X	X	1	X	X	X	X	X
16800	-	-	X	X	X	X	X	X	X	1	X	X	X	X	X	X
19200	-	-	X	X	X	X	X	X	1	X	X	X	X	X	X	X
21600	-	-	X	X	X	X	X	1	X	X	X	X	X	X	X	X
24000	-	-	X	X	X	X	1	X	X	X	X	X	X	X	X	X
26400	-	-	X	X	X	1	X	X	X	X	X	X	X	X	X	X
28800	-	-	X	X	1	X	X	X	X	X	X	X	X	X	X	X
31200	-	-	X	1	X	X	X	X	X	X	X	X	X	X	X	X
33600	-	-	1	X	X	X	X	X	X	X	X	X	X	X	X	X

The rate mask at 383h/382h controls the data rate for both the transmitter and receiver. In other words, if the rate mask is limited to 24k bps, both the transmitter and receiver rates will be limited to 24k bps. If connected in asymmetric mode (see Function 86) the transmitter rate may be further limited by the request of the remote modem's receiver. In symmetric mode, the transmitter and receiver rates cannot differ and will end up at the highest common rate between the two modems, at or below the maximum common data rate specified in both modem's rate mask.

The transmitter and receiver rates can alternatively be limited independently through addresses 605h and 604h, respectively. Note that only the maximum rate can be limited and not specific rates as with the mask at 383h/382h. See Section 14.

The rate masks will limit the data rates during the initial handshake, retrains and rate renegotiations. The rate masks will also limit (but not increase) any speed decision made by the ARA or the manual data rate selection as described in Section 14.

Function 86: V.34 Asymmetric Data Rates Enable **Acc Method: 1** **Address: 13Fh:6**

V.34 modes normally operate with asymmetric data rates for the transmitter and receiver. Resetting (default state) bit 13Fh:6 (Function 85) forces the transmitter and receiver data rates to be the same. Setting bit 13Fh:6 allows the transmitter data rate to be different than the receiver data rate.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 87: **V.34 Remote Modem Data Rate Capability**
 V.34 Remote Modem Asymmetric Data Rate

Acc Method: 2
Acc Method: 1

Address: 209h, 208h
Address: 209h:7

The data rate capability of the remote modem is reflected in a binary sequence transmitted by the remote modem during Phase 4 of the handshake. This 12-bit received sequence is stored in locations 208h and 209h (Table 4-8). The definition of this field is the same as that described for the V.34 Data Rate Mask (Function 84). Also stored in bit 7 of 209h is the capability of the remote modem to support asymmetric data rates (if set, then capability is enabled). This information is valid after RLSD is ON. The received V.34 rate sequence indicates the remote modem's true speed capabilities as it is masked only by the remote mask sequence register and not by the remote ARA function (EARC bit = 1). For example, the MDP may connect at 24000 bps by request of the remote modem's ARA, yet the received rate sequence may indicate that the remote modem can support 28800 bps. This information may be used for fall forward decisions. Bits 14-15 are reserved.

Table 4-8. V.34 Remote Modem Data Rate Capability Bit Assignments

Data Rate (bps)	V.34 Remote Modem Data Rate Capability -MSB (Address 209h)								V.34 Remote Modem Data Rate Capability-LSB (Address 208h)							
	B15	B14	B13	B12	B11	B10	B9	B8	B7	B6	B5	B4	B3	B2	B1	B0

Function 88: **V.8 Status Registers - See Section 9.**

Function 89: **V.8 Control Registers - See Section 9.**

Function 90: **Modulation Modes- See Section 9.**

Function 91: **V.8 MaxFrameByteCount- See Section 9.**

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 100: Minimum On Time (DTMF)

Acc Method: 3

Address: E96h

The minimum on time is defined as the minimum period of time of the DTMF signal beginning when the signal is detected and ending when the energy is below the turn-off threshold. The on-time parameter cannot be set below 20 ms (0000h). The default on-time parameter is set for 40.0 \pm 1 ms. The on-time will vary with signal level. To increase or decrease the on-time parameter value, convert the increase/decrease into hexadecimal and add/subtract to/from the current value.

Format: 16 bits, twos complement, positive value

Range: 0000h to 7FFFh

Equation: Minimum On Time \pm [(Increase/Decrease)Sample Rate]h

Function 101 Minimum Off Time (DTMF)

Acc Method: 3

Address: C96h

The minimum off time is defined as the minimum period of time of the DTMF signal beginning when the energy falls below the turn-off threshold and ending when a gain hit is detected. The off-time parameter is equal to the desired minimum off-time minus the drop out time. The default off time is set for 40.0 \pm 1 ms with a default dropout time parameter of 5.0 ms. To increase or decrease the off-time parameter value, convert the increase/decrease into hex and add/subtract to/from the current value.

Format: 16 bits, twos complement, positive value

Range: 0000h to 7FFFh

Equation: Minimum Off Time \pm [(Increase/Decrease)Sample Rate]h (dropout time equal to 5.0 ms).

Function 102: Minimum Cycle Time (DTMF)

Acc Method: 3

Address: D96h

The minimum cycle time is defined as the minimum period of the DTMF signal beginning when the signal is detected and ending when the next signal begins. The cycle time parameter is equal to the desired minimum cycle-time minus the dropout time. The default cycle time parameter is set for 93.0 \pm 1 ms with a default drop out time parameter of 5.0 ms. To increase or decrease the cycle time parameter value, convert the increase/decrease into hex and add/subtract to/from the current value.

Format: 16 bits, twos complement, positive value

Range: 0000h to 7FFFh

Equation: Minimum Cycle Time \pm [(Increase/Decrease)Sample Rate]h (dropout time equal to 5.0 ms).

Function 103: Minimum Dropout Time (DTMF)

Acc Method: 3

Address: F96h

The minimum dropout time is defined as the maximum period of the DTMF signal beginning when the signal energy drops below the turn-off threshold and ending when the signal energy returns that is considered to be part of the on time. The default dropout time parameter is set to 5.0 ms.

Format: 16 bits, twos complement, positive value

Range: 0000h to 7FFFh

Equation: [(Desired time)Sample Rate]h

Function 104: Maximum Speech Energy (DTMF)

Acc Method: 3

Address: E95h

This parameter specifies the maximum relative speech energy that may be detected and still receive DTMF signals. The speech energy is measured in the frequency region of second or third harmonics of the DTMF tones. To disable the speech energy detector, set this parameter to its full scale positive value (7FFFh). Decreasing the value of this parameter may degrade signal-to-noise ratio (SNR) performance, but may reduce false settings of status bit EDET due to speech signals. To increase or decrease the maximum speech energy parameter value, convert the increase/decrease into hex and add/subtract to/from the current value.

Format: 16 bits, twos complement, positive value

Range: 0000h to 7FFFh

Equation: Maximum Speech Energy \pm (Increase/Decrease)h

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Function 105: Frequency Deviation, Low Group (DTMF) Acc Method: 3 Address: C94h

This parameter controls the acceptable frequency range for the low group DTMF tones (697, 770, 852, and 941 Hz). Increasing the value of this parameter increases the frequency range. The frequency range will vary from one DTMF symbol to another. To increase or decrease the parameter value, convert the increase/decrease into hex and add/subtract to/from the current value.

Format: 16 bits, twos complement, positive value
Range: 0000h to 7FFFh
Equation: Frequency Deviation \pm (Increase/Decrease)h

Function 106: Frequency Deviation, High Group (DTMF) Acc Method: 3 Address: E94h

This parameter controls the acceptable frequency range for the high group DTMF tones (1209, 1336, 1477, and 1633 Hz). Increasing the value of this parameter increases the frequency range. The frequency range will vary from one DTMF symbol to another. To increase or decrease the parameter value, convert the increase/decrease into hex and add/subtract to/from the current value.

Format: 16 bits, twos complement, positive value
Range: 0000h to 7FFFh
Equation: Frequency Deviation \pm (Increase/Decrease)h

Function 107: Negative Twist Control, TWIST4 (DTMF) Acc Method: 3 Address: D95h

This parameter controls the acceptable negative twist for the DTMF signals. Decreasing this parameter increases the acceptable negative twist level. The twist will vary from one DTMF symbol to another. To increase or decrease the parameter value, convert the increase/decrease into hex and add/subtract to/from the default value.

Format: 16 bits, twos complement, positive value
Range: 0000h to 7FFFh
Equation: Negative Twist \pm (Increase/Decrease)h
Default: 18CEh

Function 108: Positive Twist Control, TWIST8 (DTMF) Acc Method: 3 Address: C95h

This parameter controls the acceptable positive twist for the DTMF signals. Decreasing this parameter increases the acceptable positive twist level. The twist will vary from one DTMF symbol to another. To increase or decrease the parameter value, convert the increase/decrease into hex and add/subtract to/from the default value.

Format: 16 bits, twos complement, positive value
Range: 0000h to 7FFFh
Equation: Positive Twist \pm (Increase/Decrease)h
Default: 1B2Dh

Function 109: Maximum Energy Hit Time (DTMF) Acc Method: 3 Address: E87h

This parameter represents the duration of an allowed energy impulse during the off time measurement. The default value of 0000h means no gain hits will be tolerated during the off time.

Format: 16 bits, twos complement, positive value
Range: 0000h to 7FFFh
Equation: [(Desired Time)(Sample Rate)]h

Function 110: ADC Speech Sample Scaling Parameter, ADCS (ADPCM Rx-coding) Acc Method: 3 Address: F21h

The received signal sample is scaled by parameter ADCS prior to ADPCM compression by the Rx-coder. Decreasing the value of this parameter attenuates the received speech samples.

Format: 16 bits, twos complement, positive value
Range: 0000h to 7FFFh
Default: 7FF0h

5. HDLC OPERATION

The HDLC (High Level Data Link Control) protocol is a standard procedure used for data communications. SDLC (Synchronous Data Link Control) is a bit-oriented protocol which is a subset of HDLC. The same format is used in both protocols although all SDLC fields must be eight-bit octets. The MDP uses the SDLC protocol but it is referred to as HDLC to avoid confusion.

5.1 HDLC FRAMES

Data and control information on a HDLC link are transmitted via frames. These frames organize the information into a format specified by an ISO standard that enables the transmitting and receiving stations to synchronize with each other. This format is shown in Figure 5-1. Flags and the frame check sequence are distinguished from the other fields by status bits in the MDP interface memory.

Flags

All frames start and end with a flag sequence. The beginning flag and the ending flag are defined by the bit pattern 01111110 (7E). The ending flag for one frame can also serve as the beginning flag for the following frame. If separate ending and beginning flags are used, the final zero in the ending flag of one frame may also serve as the first zero of the beginning flag in the following frame. This process is known as "zero-sharing". The zero-sharing bit pattern is 011111101111110.

Address Field

The address field informs the receiver where the information is to go (if the primary station is transmitting) or where the message originated (if a secondary station is transmitting). This field is eight bits in length for the "basic" format.

For the "extended" format, the length is N number of octets, each octet having the first bit a binary zero with the exception of the last octet that begins with a binary one.

Control Field

The control field defines the function of the frame. It may contain a command or response. The control field might also contain send or/and receive sequence numbers. This field can be in one of the following formats:

1. Information Transfer Format
2. Supervisory Format
3. Unnumbered Format

This field is normally eight bits in length. Certain protocols allow for an extended control field of 16 bits in length.

Information Field

The MDP does not distinguish between the address field, the control field, or the information field. The information field does not have a set length; however, this field is in the SDLC protocol format of 8-bit bytes.

Zero Insertion

Since flags mark the beginning and ending of a frame, some method must be implemented to inhibit or alter the transmission of data that appear as flags. The method used is called "zero insertion". HDLC procedures require that a zero be transmitted following any succession of five continuous ones. This includes all data in the address, control, information and Frame Check Sequence (FCS) fields. Use of zero insertion denies any pattern of 01111110 to ever be transmitted between beginning and ending flags.

The MDP transmitter always performs zero insertion when in HDLC mode.

Zero Deletion

When transmitting flags, zero insertion is disabled. During reception of data, after testing for flag recognition, the receiver removes a zero that immediately follows five continuous ones. This is termed "zero deletion". A one that follows five continuous ones signifies either a frame abort (i.e., at least seven ones with no zero insertion) or a flag (i.e., 01111110). The sixth one is, therefore, not removed.

The MDP receiver always performs zero deletion when in HDLC mode.

Figure 5-1. HDLC Frame

Frame Check Sequence

The purpose of the Frame Check Sequence (FCS) is to give a shorthand representation of the entire transmitted information field and to compare it to the identically generated shorthand representation of the received sequence. If any difference occurs, the received frame was in error and should be re-transmitted.

The FCS computation is done on all fields within the frame but does not include the flags. A standard Cyclic Redundancy Check (CRC) is used to compute the FCS. Either 16-bit (CRC16) (default) or 32-bit (CRC32) CRC may be selected using the ITU-T CRC32 RAM parameter (see parameter 52 in Section 4.4). The CRC polynomials are:

$$\text{CRC16} = x^{16} + x^{12} + x^5 + 1 \quad (\text{SDLC and X.25})$$

$$\text{CRC32} = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + 1$$

The FCS is sent as two bytes of data immediately preceding the ending flag of the frame. The FCS register is first preset to all binary ones. The register is then modified by shifting in the data (no flags) contained in the address, control, and information fields. Following the last bit of data, the ones complement of the FCS register is transmitted as the FCS. The FCS is transmitted with the highest order bit first.

To disable the CRC transmission in HDLC mode, set bit 0B3h:6. This is needed for H.324 applications.

Frame Abortion, Frame Idle, and Time Fill

Frame abortion prematurely finishes transmission of a frame. This occurs by sending at least seven consecutive ones with no zero insertion. This abort pattern terminates a frame immediately and does not require a FCS or an ending flag.

An abort pattern followed by a minimum of eight additional consecutive ones idles the data link. Thus, seven to fourteen ones establish the abort pattern; fifteen or more ones constitute an idle pattern.

Interframe time fill is accomplished by transmitting continuous flags.

By default, if the host underruns the Transmit FIFO, the MDP will append a CRC. If bit 3A5h:6 is set, the MDP will instead abort the frame and provide an abort code of 41h in ABCODE.

5.2 HDLC AND FIFO DATA BUFFERS

5.2.1 Transmit and Receive FIFO Data Buffers

Two 16-byte first-in first-out (FIFO) data buffers, in conjunction with 128-byte buffer extension (see Section 4, Function 74), allow the DTE/host to rapidly output up to 144 bytes of transmit data and input up to 144 bytes of accumulated receive data. The receiver FIFO is always enabled. The transmitter FIFO is enabled by the FIFOEN control bit. The TXHF and RXHF bits indicate the corresponding FIFO buffer half full (4 or more bytes loaded) status. The TXFNF and RXFNE bits indicate the TX FIFO buffer not full and RX FIFO buffer not empty status, respectively. An interrupt mask register allows an interrupt request to be generated whenever the TXFNF, RXFNE, RXHF, or TXHF status bit changes state.

5.2.2 RX FIFO and HDLC Operation

The RXFIFO is a 12-bit wide FIFO; 8 bits for data and 3 bits of HDLC status (FE, PE, SYNCD). The bit OE is used to indicate an overrun condition and is set immediately upon an overrun condition, it is not buffered like the SYNCD, PE, and FE bits. If a byte is received as a FLAG, then 7E is stored in the data portion of the FIFO (RBUFFER) and the SYNCD bit is set (PE is set if there are CRC errors). (See Figure 5-2 and Figure 5-3.) The status bits must be read BEFORE reading the data bits because reading the data moves the FIFO pointer to the NEXT byte effectively overwriting the prior status bits.

If, in HDLC mode, 8 zeros appear at the receiver (intentional or otherwise), the HDLC processor will load them in the RX FIFO as data, but when the next flag is received a CRC error (PE set) will appear with it.

SYNCD will come on with the FIRST flag and the 7E will appear in the buffer. Again, when servicing the RDBF interrupt, the status bits (i.e., SYNCD must be read first.) The remaining 7Es, however long the string, will not be sent through the RX FIFO. The next data/error pair sent through the FIFO will be data (i.e., SYNCD off) or perhaps an abort (FE = 1).

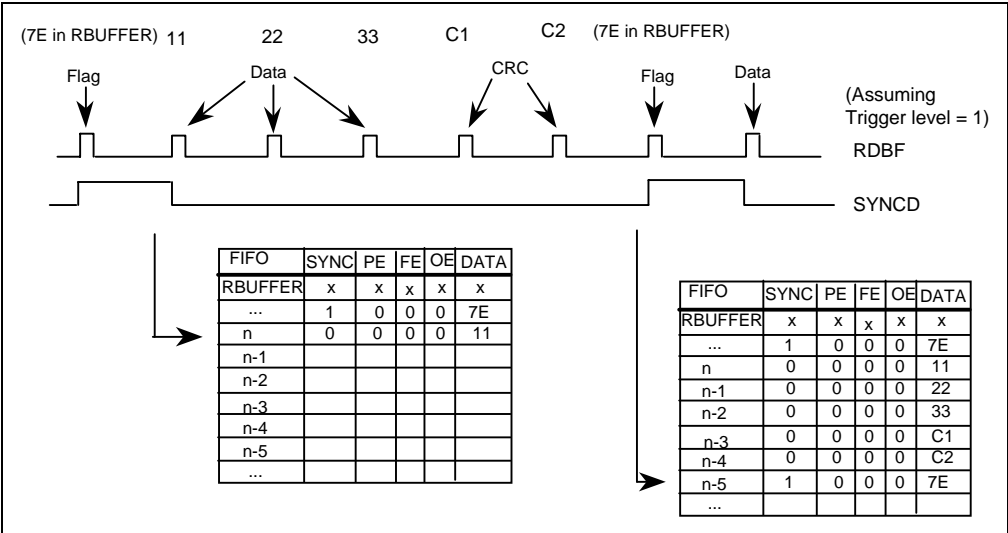

Figure 5-2. Normal HDLC Receive Operation

Note that the RDBF interrupts in the figures assume a trigger level of 1. If the trigger level is greater, the data bytes and status bits will still be loaded in the FIFO (at the same time as RDBF would have been set if the trigger level was set at 1) but RDBF will not be set.

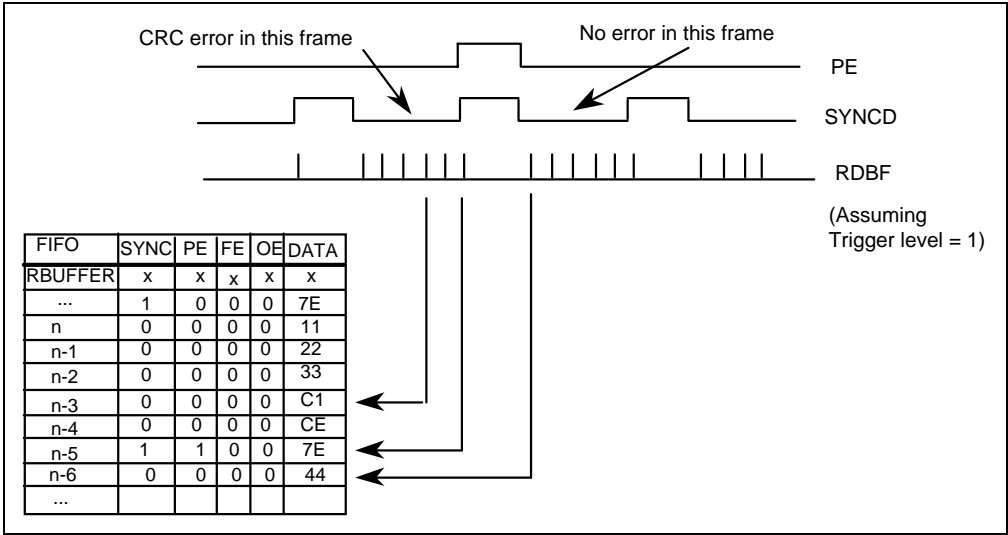

Figure 5-3. HDLC Receive Operation when a CRC Error Occurs

The FE bit indicates that an abort has been detected. Figure 5-4 shows the relationship of the FE bit to the SYNCND bit. The MDP will set only the FE bit when an abort is received. The MDP will also provide an RDBF interrupt (assuming trigger level is 1) and the RBUFFER will contain a FFh which should be discarded. The FE bit will be cleared before receiving the first byte of the next valid frame.

Figure 5-4. HDLC Receiver Operation with an Abort Condition

The OE bit will be set when a received byte does not have room in the RXFIFO. That byte and all others that follow will not be placed in the RXFIFO as long as the RXFIFO is full. The OE bit must be reset by the host.

In many applications, there is little reason to enable NSIE when doing HDLC RX in this device. Simply use the RDBF (or RXHF or RXFNE). Read the status bits first. If SYNC and FE are off, then read RBUFFER and store as data. When SYNC is on, and PE is off, the last frame (if there was one) is valid. If SYNC = 1 and PE = 1, then there were CRC error(s) in the last frame so trash it. If FE = 1, then an abort condition has occurred so trash the frame.

Also make sure to purge the 7E from RBUFFER when SYNC = 1 and also to purge the FFh when FE = 1.

5.3 OPERATION

5.3.1 Transmitter and Receiver Setup

To select HDLC mode, the host must:

1. Set the CONF bits to the desired MDP configuration. HDLC can be used in all data modes except the full-duplex FSK modes (i.e., V.21, V.23, and Bell 103).
2. Reset the ASYN bit to select synchronous mode, if not already in synchronous mode.
3. Set the TPDM bit to select Transmitter Parallel Data Mode (transmitting only). Setting TPDM is not required when receiving since received data is always available in RBUFFER. Note that HDLC transmission cannot be performed using the serial interface (TPDM = 0).
4. Set the FIFOEN bit to enable the TXFIFO if desired.
5. Set the RTS bit to turn on RTS (transmitting only).
6. Set the HDLC bit to select HDLC mode.
7. Set the NEWC bit.

5.3.2 Transmitter HDLC Operation

The format of the data input to the MDP is in groups of 8-bit bytes. As in the normal synchronous parallel data mode, the least significant bit of the byte is transmitted first.

Flag Transmission and Reception

In HDLC mode, the MDP will send continuous flags with no zero sharing (i.e., 011111100111..) until the host loads data into the Transmit Data Buffer, TBUFFER (10h). Thus, the MDP defaults to transmitting time-fill and keeps the receiving link station active. The status bit FLAGS (0Ah:1) is set to indicate that the MDP is transmitting the flag sequence.

Information Field Transmission and Reception

If the FIFO is not enabled (FIFOEN bit = 0), if the next byte is not loaded into TBUFFER within the next eight bit times, the MDP interprets this as the end of a frame. If the FIFO is enabled (FIFOEN bit = 1), the TEOF bit must be set by the host to indicate that the next byte to be written into TBUFFER is the last byte in the frame. The host must reset the TEOF bit after writing the last byte of the current frame and before writing the first byte of the next frame.

FCS and Ending Flag Transmission and Reception

Following the detection end of frame (by means of underrunning or use of TEOF), the MDP automatically sends the FCS and ending flag. Status bit CRCS (0Ah:2) is set just before the highest order bit is sent to indicate that the FCS is being transmitted. When FIFOEN = 0, the first byte of the next frame can be loaded when CRCS is set. If FIFOEN = 1, the first byte of the next frame can be loaded as soon as TEOF is cleared by the host. In this case, the ending flag serves as the beginning flag for the next frame. The MDP resets the CRCS bit when the ending flag is transmitted. At the same time, the MDP sets the FLAGS bit.

After the FCS transmission (immediately following bit x0), the MDP sends one flag to signify the end of the current frame and the beginning of the next frame. After the final zero in a flag is transmitted, the MDP looks to see if the host has loaded new data into TBUFFER. If no new data is loaded before this time, another flag is sent. The number of flags sent between the frames can be programmed in address 2A6h; 00h (default) = 1 flag, 01h = 2 flags, 02h = 3 flags, and so on.

Abort/Idle Sequence Transmission and Reception

An abort/idle sequence can be sent by the host setting the MHLID bit (07h:0). The MDP stops sending any normal frame transmission, as well as continuous flag transmission, and sends continuous ones. To stop sending continuous ones, the host must reset MHLID. Then, if no new data is loaded into TBUFFER, the MDP sends continuous flags. If new data is loaded into TBUFFER, the MDP sends a beginning flag and then the data in TBUFFER.

5.3.3 Receiver HDLC Operation

The format of the data output to the host is in groups of 8-bit bytes. As in the normal synchronous parallel data mode, the least significant bit of the byte is transmitted first.

Flag Transmission and Reception

The MDP receiver continually searches for the flag data pattern. When one or more flags are detected, status bit SYNCID (0Ah:0) is set. The flags themselves are not presented to the host through the receiver data buffer RBUFFER (00h). The host must service the RDBF interrupt while waiting for the SYNC bit to be set to a 1 in order to clear the Receive FIFO of any unwanted or left-over characters and to ensure the alignment of the SYNCID bit with the received flag.

The MDP can also detect consecutive flags with zero-sharing.

Information Field Transmission and Reception

Received data between flags is passed to the host through the RBUFFER by the use of the handshaking bit RDBF (1Eh:0). The host must wait for RDBF to be set by the MDP before reading the status bits, followed by the received data in RBUFFER. Note that the RBUFFER and Receive FIFO can accumulate 144 bytes before overflowing. If the host does not read the data within 16 byte times, the data in RBUFFER will be overwritten by the next received byte and the Overrun Error bit (0Ah:3) will be set. The flag sequence and abort/idle sequence are not presented to the user. The receiver determines where the FCS field is by detecting the ending flag. There is at least a 16-bit time delay in the reception of data.

FCS and Ending Flag Transmission and Reception

Upon the receipt of an ending flag in the current frame (which may also be the beginning flag of the next frame), the receiver checks the data in the FCS register. If the FCS register remainder is correct, the PE bit (0Ah:5) is left a zero. If the remainder is incorrect, the PE bit is set. The FCS field is also passed to the host, in case the host wishes to do his own CRC checking. The receiver will set the SYNCID bit and the PE bit (if the MDP detected a frame with a bad CRC) after sending the FCS to the host. The MDP presets the FCS register to all ones after one or more flags are received.

After the FCS transmission (immediately following bit x0), one flag is sent to signify the end of the current frame and the beginning of the next frame. After the final zero in a flag is transmitted, the MDP looks to see if the host has loaded new data

into TBUFFER. If no new data is loaded before this time, another flag is sent. Therefore, if more than one flag between frames is desired, the host must wait $N-1$ multiples of eight bit times after FLAGS is set by the MDP to load new data into TBUFFER, where N is the number of flags. The host then has seven bit times in which to load new data and thus prevent another flag from being sent. For example, if three flags are desired between frames, the host must wait at least 16 bit times and not more than 23 bit times after FLAGS is set by the MDP.

Abort/Idle Sequence Transmission and Reception

The MDP receiver not only continually searches for flags, but also continually searches for an abort/idle sequence. When the MDP detects this data pattern, it sets the FE bit (0Ah:4). The reception of data following the abort/idle sequence is treated as invalid data and is not presented to the host. Therefore, to re-establish transmitter and receiver synchronization, the receiver must see at least one flag. If FE is set, the current received data byte (typically FFh) should be discarded.

5.4 EXAMPLE APPLICATION

Refer to Table 3-1 for a description of the bits associated with the HDLC functions. Figure 5-5 illustrates bit timing.

5.4.1 Transmitter Example (Tx FIFO Disabled)

The steps to perform a typical HDLC transmission with the Transmitter FIFO disabled are (Figure 5-5a):

1. Set the MDP configuration in CONF; reset the ASYN and FIFOEN bits; set the HDLC, TPDM, and RTS bits.
2. The MDP starts transmitting flags immediately and continues with flags until the first byte of data is loaded into TBUFFER.
3. Wait for TDBE = 1, then place the first byte of data into TBUFFER. The MDP finishes transmitting the current flag followed by this byte of data.
4. As soon as TDBE is set, load in the next byte of data. This must occur within 2.5 bit times of TDBE being set.
5. After all information but the last byte is given to the MDP, load in the last byte of data in the frame as in step 4.
6. Wait until FLAGS is set to load in the first byte of the next frame. The MDP follows the last byte of the current frame with the FCS and a flag.
7. Repeat steps 4 through 6 for all frames to be transmitted.

5.4.2 Transmitter Example (Tx FIFO Enabled)

The steps to perform a typical HDLC transmission with the Transmitter FIFO enabled are:

1. Set the MDP configuration in CONF; reset the ASYN bit; set the FIFOEN, HDLC, TPDM, and RTS bits.
2. The MDP starts transmitting flags immediately and continues with flags until the first byte of data is loaded into TBUFFER.
3. Place the first byte of data into TBUFFER. The MDP finishes transmitting the current flag followed by this byte of data.
4. Continue to load data in TBUFFER until TXFNF = 0 or the last byte of the frame is reached.
5. After all information but the last byte is given to the MDP, set TEOF, then load in the last byte of data in the frame as in step 4.
6. Reset TEOF to 0.
7. Repeat steps 4 through 6 for all frames to be transmitted.

5.4.3 Receiver Example

The steps to perform a typical HDLC reception are (Figure 5-5b):

1. Set the MDP configuration in CONF; reset the ASYN bit; set the HDLC bit. Then monitor, through interrupts, the RDBF, OE, SYNCN, PE, and FE status bits.
2. Wait for an interrupt. If it is caused by the MDP setting RDBF (RDBIA is also set by the MDP), if NEWS = 1 or NSIA = 1, read status bits OE, SYNCN, PE, and FE.
OE indicates that RBUFFER was loaded with new data before the host read the old data.
SYNCN indicates that the MDP is receiving flags (RBUFFER = 7E).
PE indicates that the FCS had an incorrect CRC.
FE indicates that an abort/idle sequence is detected (RBUFFER = FF) and the frame that was aborted is invalid. The MDP does not set the PE bit in this case since no FCS checking is done.
3. If NEWS = 0 and RDBF = 1 (or RXFNF = 1), read the received data in RBUFFER. **Note:** The host may continue to read the HDLC status bits followed by RBUFFER until the RXFIFO is empty, i.e., RDBF = 0 (or RXFNE = 0).
4. Continue waiting for interrupts and take appropriate action when the interrupts are received.

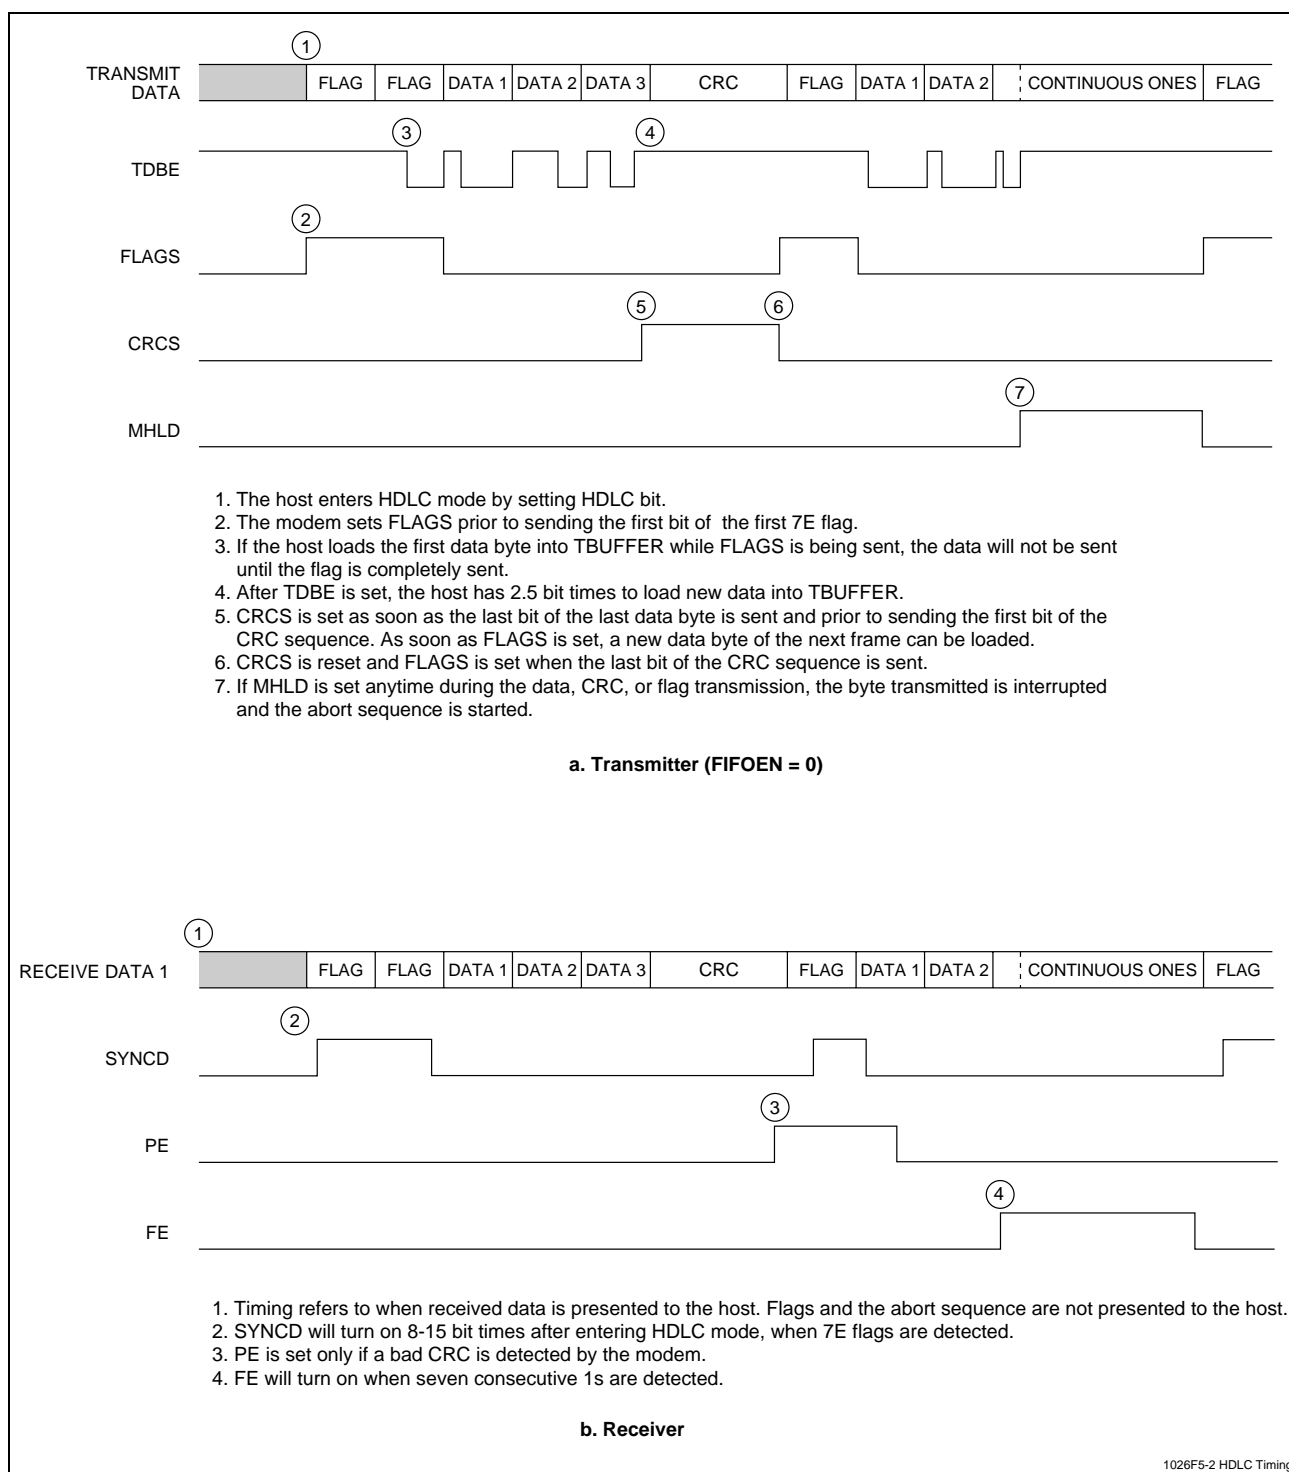

Figure 5-5. HDLC Signal Timing

6. HOST FUNCTIONS

6.1 INTERRUPT REQUEST HANDLING

DSP interface memory registers 00, 10, 1E, and 1F have unique hardware connections to the interrupt logic. Register 00 is the Receive Buffer (RBUFFER) and register 10 is the Transmit Buffer (TBUFFER). Registers 1E and 1F hold interrupt flag, interrupt enable, and interrupt active bits. When a condition occurs that satisfies an interrupt criteria, the corresponding interrupt flag bit is set. This interrupt flag can be reported to the host either by the host polling the interrupt flag bits (i.e., not using IRQ) or by being interrupted by IRQ. When an interrupt enable bit is a 1, IRQ is asserted and the appropriate interrupt active bit set to a 1 when the corresponding interrupt condition occurs.

The basic sources for IRQ generation are status change detected (status bit changes state, maskable in DSP RAM), configuration change implemented, receive buffer full, transmit buffer empty, and memory access (also maskable in DSP RAM). Each source is individually maskable.

Table 6-1 identifies the interrupt sources and describes the interrupt clearing procedures.

6.2 AUTO DIAL PROCEDURE

The host auto dial procedure is the same as outputting data to be transmitted using TBUFFER (Figure 6-1). The MDP timing accounts for the DTMF tone duration and amplitude, and inter-digit delay. These dialing parameters are host programmable in DSP RAM.

Calling tone on/off times are also programmable in DSP RAM. Calling tone levels are controlled by the Transmit Level bits (TLVL).

The levels of the high band and low band DTMF tones may be modified by the host in DSP RAM. The level of the high band DTMF tone should be 2 dB greater than the level of the low band DTMF tone. Transmit Level bits (TLVL) do not affect DTMF levels.

The auto dialer default parameters are given in Table 6-2.

6.3 AUTO MODE DETECTION

Figure 6-2 and Figure 6-3 show the flowcharts corresponding to the DSP algorithm used in supporting originating and answering automode (AUTO 15h:3), respectively.

Table 6-1. Interrupt Request Bits

Interrupt Active Bit	Interrupt Enable Bit	Interrupt Flag Bit	Interrupt Condition Description	Interrupt Clear Procedure
NSIA	NSIE	NEWS	New status detected (NEWS transitioned from a 0 to 1) a. RAM read or RAM write occurred b. Status bit changed in register 0A-0F, 01, 12, 14, 16-17, 1A, or 1B	Host writes a 0 into NEWS (Clears NSIA to a 0)
NCIA	NCIE	NEWC	New configuration implemented by the MDP (NEWC transitioned from a 1 to a 0).	Host writes a 0 into NCIE (Clears NCIA to a 0)
TDBIA	TDBIE	TDBE	TBUFFER is empty and can be written (TDBE transitioned from a 1 to a 0)	Host writes to BUFFER (10h:7-0) (Clears TDBE and TDBIA to 0)
RDBIA	RDBIE	RDBF	RBUFFER is full and can be read (RDBF transitioned from a 0 to a 1).	Host reads RBUFFER (00h:7-0) Clears RDBF and RDBIA to 0)

Table 6-2. Auto Dial Default Values

Parameter	Default Value
DTMF Tone Duration	92 ms
DTMF Interdigit Delay	72 ms
DTMF Total Output Power Level	0 dBm
DTMF Low Band Power Level	-4 dBm
DTMF High Band Power Level	-2 dBm
Pulse Relay Make Time	36 ms
Pulse Relay Break Time	64 ms
Pulse Interdigit Delay	750 ms
Calling Tone On Time	500 ms
Calling Tone Off Time	2 s

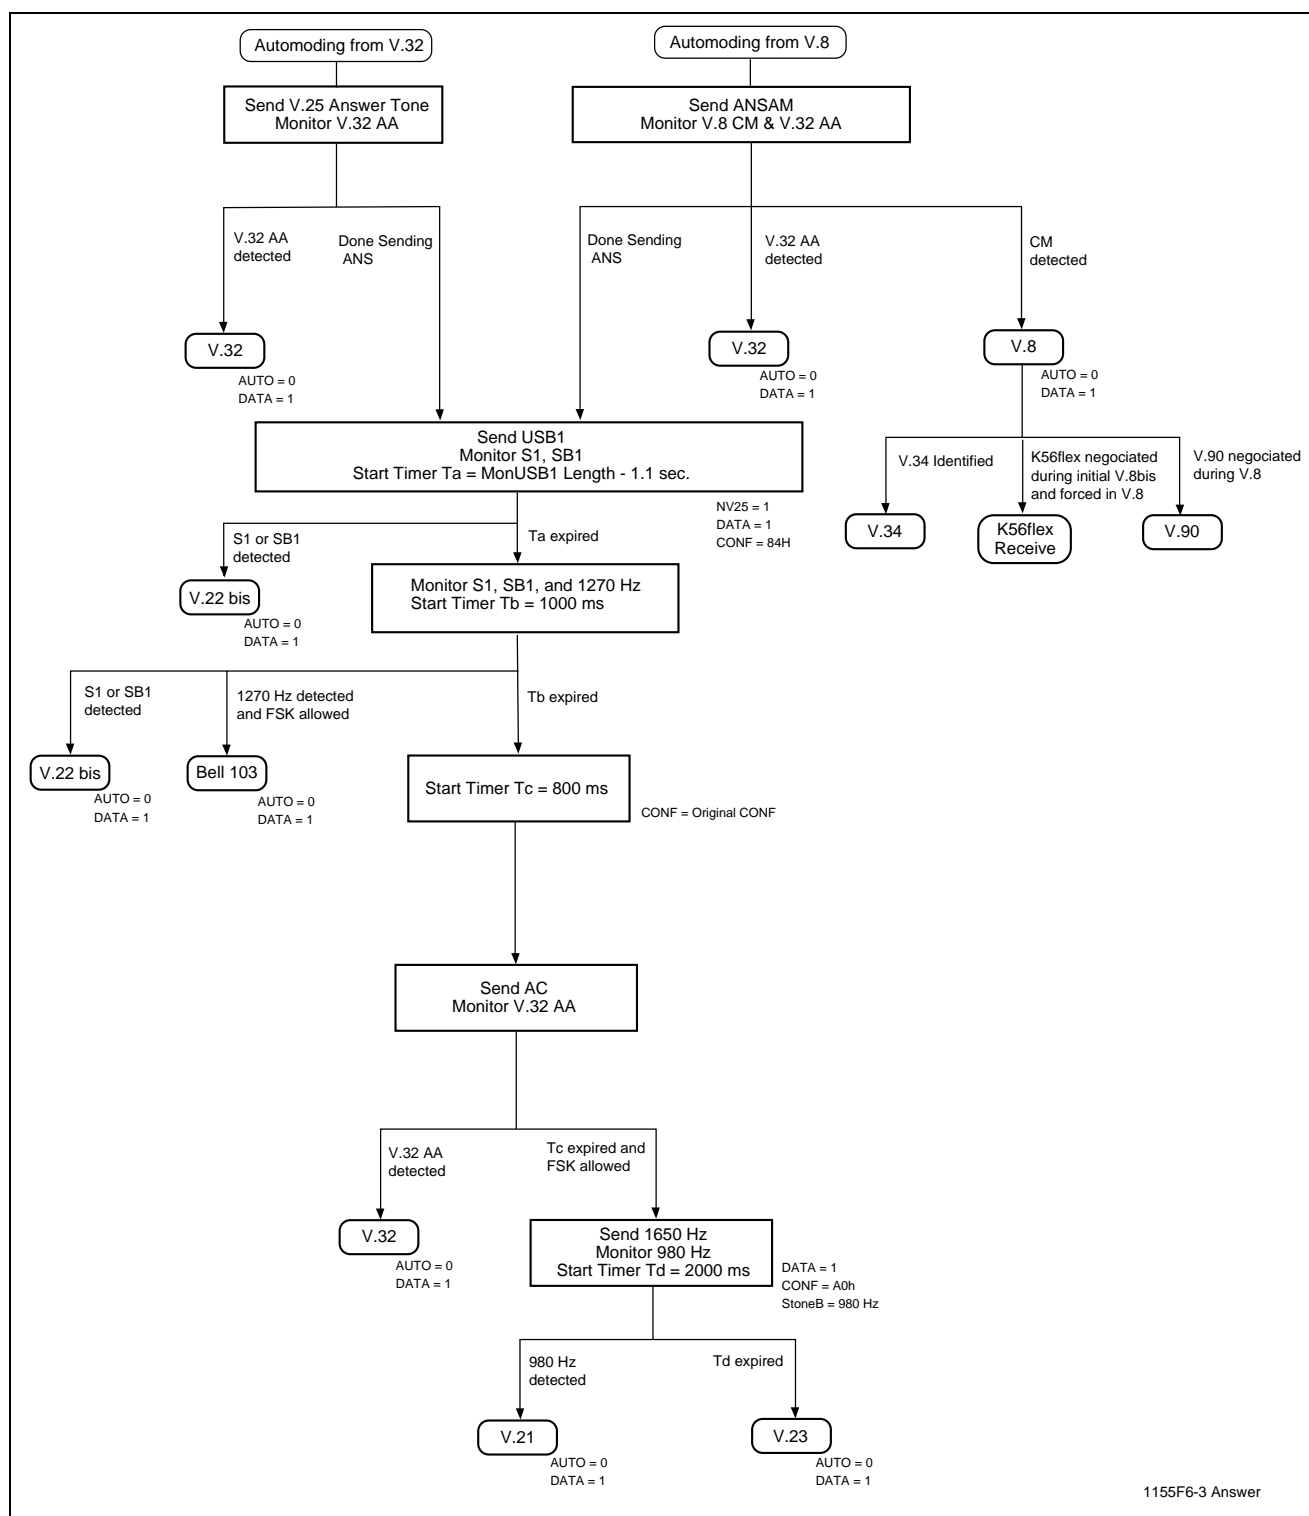

Figure 6-3. Host Flowchart - Answering Automode

6.4 MODEM SELF-TEST INFORMATION

After a power-on reset, the MDP performs a self-test of the internal controller and DSP devices. After each self-test, the test results and configuration information is loaded into interface memory.

Figure 6-4 shows the flowchart for reading the self-test data.

6.4.1 Controller Self-Test

The controller self-test is performed first. Upon test completion, the following test results and configuration information is loaded into interface memory:

Register	Function	L8570		L8771	
		Value (Hex)*	Value Type	Value (Hex)*	Value Type
1D, 1C	RAM1 Checksum	EA3C	Constant	0451	Constant
1B, 1A	RAM2 Checksum	5536	Constant	49A5	Constant
19, 18	ROM1 Checksum	5F4C	Constant	5F4C	Constant
17, 16	ROM2 Checksum	3835	ASCII 85	3836	ASCII 86
15, 14	Timer/ROM/RAM	0801	Constant	DE00	Constant
13, 12	Part Number	3730	ASCII 70	3731	ASCII 71
11, 00	Revision Level	4241	ASCII BA	4241	ASCII BA
* Values shown are typical and may not reflect the current code release.					

The host should read the test results within 5 ms of the appearance of RAM1 and RAM2 checksums. Register 10 should then be read to reset bit 1Eh:3 (ignore the read value).

When bit 1Eh:3 is reset or 5 ms has expired, the information is cleared and the DSP self-test is performed. If the register 10 is not read by the host, bit 1Eh:3 will not be reset.

6.4.2 DSP Self-Test

Upon completion of DSP self-test, the following test results and configuration information is loaded into interface memory and bit 1Eh:3 is set to a 1:

Register	Function	L8570		L8771	
		Value (Hex)*	Value Type	Value (Hex)*	Value Type
1B, 1A	EC Checksum	F083	Constant	A577	Constant
19, 18	Multiplier Checksum	46EE	Constant	46EE	Constant
17, 16	RAM Checksum	00FA	Constant	B482	Constant
15, 14	ROM Checksum	0A09		3836	ASCII 86
13, 12	Part Number	3730	ASCII 70	3631	ASCII 61
11, 00	Revision Level	2041	ASCII A	2041	ASCII A
* Values shown are typical and may not reflect the current code release.					

The host should read the test results within 5 ms of bit 1Eh:3 being set.

When bit 1Eh:3 is reset or 5 ms has expired since DSP test completion, the information is cleared and MDP initialization continues.

Soft Reset. If reading the self-test information by performing a soft reset (see SFRES in Table 3-1), set SFRES, then set NEWC (do not wait for NEWC to clear). Proceed as described above. After reading the desired information, wait for NEWC to clear, plus a minimum of 10 ms, before accessing the MDP.

NOTE: The reset time for both a hard or soft reset is under 150 ms.

Figure 6-4. Modem Self-Test Results Read Procedure

6.5 EQM AVERAGING

A host-programmable EQM averaging feature helps the host controller with retrain and rate change decisions. A single-pole low-pass filter is used to average the EQM samples. The number of symbol intervals between EQM samples is host-programmable in memory location 26Bh (*EQMBaudInterval*). Also, the host can program the number of EQM samples to be used before the final filtered EQM value (*FilteredEQM*) is determined. The EQMAT bit is set if this final *FilteredEQM* (address 26Fh) is larger than the EQMAT threshold (address 133h). If *EQMBaudInterval* is 0, then the EQM averaging is disabled as is by default. Suitable values for addresses 26Bh and 26Ch are 20h and 64h, respectively. They may be altered as desired. The value obtained at address 26Fh is the same as if the host were to read and average the MSB of EQM read at address 20Ch (Function 46). All RAM accesses are 8-bit.

Parameter Name	Address (Hex)	Default Value	Description
EQM Baud Interval	26B	0	Symbols between EQM samples used as input to LPF.
Num EQM Samples	26C	0	EQM samples to be run through the EQM LPF.
Saved Filtered EQM	26F		Output of EQM filter used for EQMAT determination (MSB value).

6.6 RETRAIN AND AUTOMATIC RATE CHANGE

This section explains how to perform the retrain and rate change.

6.6.1 Retrain Without a Rate Change

V.90/K56flex/V.34/V.32/V.32 bis and V.22 bis Configurations

When the RTRN bit is set to a 1, the MDP will initiate the retrain sequence. The modem which detects the retrain sequence will respond with training, and both modems will proceed with the proper training sequence. The retrain process can be monitored by observing the appropriate status bits in the transmitter and receiver.

6.6.2 Retrain With a Rate Change

V.90/K56flex/V.34/V.32/V.32 bis and V.22 bis Configurations

The following procedure describes how to obtain a rate change along with a retrain.

1. Store the desired configuration in the CONF register. Use configuration code 82h (V.22 bis/1200) for fall forward or fallback between 2400 bps and 1200 bps. **NOTE:** Do not set the NEWC bit.
2. Set the RTRN bit to a 1.

The MDP will then send the retrain sequence at the correct operating speed as selected in the configuration registers. The rate sequence is automatically changed in the training sequence to tell the other modem at what speed to operate. The status bits will change as mentioned above and the CTS bit will be set to a 1 when the retrain sequence is completed. (See the RREN bit description in Table 3-1 for rate change procedures in V.90/K56flex/V.34/V.32 bis modes using a rate renegotiation rather than a retrain. Also, see the SRCEN bit description in Table 3-1 for rate change procedures in V.34 mode using the secondary channel.)

6.7 HANDSHAKE TIME-OUT TIMERS

If any part of the handshake is not detected, the MDP will time out and abort the handshake. In this case, the transmitter will immediately stop sending the training sequence. Also, the MDP, upon timing out, will load an error code into register 14 (ABCODE) of interface memory that indicates that point in the handshake the time-out occurred. The error code is not cleared even if the MDP immediately goes into a new handshake after aborting. The user can observe this register during the handshake to determine if an abort occurred.

The user can progressively observe the handshake detector bits (AADET, ACDET, CCDET, SECTXD, SECRXD, etc.) to determine how the handshake is proceeding. The user can thus be interrupted at each step of the handshake progression.

The V.90, K56flex, V.34, and V.32 handshake error codes and their meanings are:

Error Code	Reason For Aborting (Time-out)
00	No error
01- FF	See ABCODE in Table 3-1 and error code definitions in Table 3-2.

6.8 CLEARDOWN

6.8.1 V.90 Cleardown

Sourcing (Locally Initiated) a V.90 Cleardown Request

1. The host loads CONF with E0h.
2. The host sets RREN to 1.

Receiving (Remotely Initiated) a V.90 Cleardown Request

1. On receiving a Cleardown request, the MDP responds by writing 96h into the ABCODE register and also writing C0h into the CONF register. RAM location 2E4h (see Section 4, Function 1) will also be cleared to zero.

6.8.2 K56flex Cleardown

Sourcing (Locally Initiated) a K56flex Cleardown Request

1. The host loads CONF with 90h.
2. The host sets RREN to 1.

Receiving (Remotely Initiated) a K56flex Cleardown Request

1. On receiving a Cleardown request, the MDP responds by writing 96h into the ABCODE register and also writing C0h into the CONF register. RAM location 2E4h (see Section 4, Function 1) will also be cleared to zero.

6.8.3 V.34 Cleardown

Sourcing (Locally Initiated) a V.34 Cleardown Request

The Cleardown procedure provided in the V.34 modes is strictly defined, and as such there is now only one method to initiate the Cleardown. The retrain method that has been provided in V.32bis is not supported in V.34. The method used is:

1. The host loads CONF with C0h.
2. The host sets RREN to 1.
3. The data pump transmits Cleardown request as per §11.7 of ITU-T Recommendation V.34.

Receiving (Remotely Initiated) a V.34 Cleardown Request

1. On receiving a Cleardown request, the MDP responds by writing 96h into the ABCODE register and also writing C0h into the CONF register. RAM location 2E4h (see Section 4, Function 1) will also be cleared to zero.

6.8.4 V.32 bis Cleardown

Sourcing a V.32 bis GSTN Cleardown Request

1. The host loads CONF with 70h.
2. The host sets either RTRN or RREN to a 1.
3. RLSD drops automatically.

Receiving a V.32 bis Cleardown Request

1. The host loads CONF with 70h.
2. RLSD drops automatically.

7. DESIGN CONSIDERATIONS

Good engineering practices must be adhered to when designing a printed circuit board (PCB) containing the MDP. Suppression of noise is essential to the proper operation and performance of the MDP itself and for surrounding equipment.

Two aspects of noise in an OEM board design containing the MDP must be considered: on-board/off-board generated noise that can affect analog signal levels and analog-to-digital conversion (ADC)/digital-to-analog conversion (DAC), and on-board generated noise that can radiate off-board. Both on-board and off-board generated noise that is coupled on-board can affect interfacing signal levels and quality, especially in low level analog signals. Of particular concern is noise in frequency ranges affecting modem performance.

On-board generated electromagnetic interference (EMI) noise that can be radiated or conducted off-board is a separate, but equally important, concern. This noise can affect the operation of surrounding equipment. Most local governing agencies have stringent certification requirements that must be met to allow use in specific environments.

Proper PC board layout (component placement, signal routing, trace thickness and geometry, etc.), component selection (composition, value, and tolerance), interface connections, and shielding are required for the board design to achieve desired modem performance and to attain EMI certification.

All the aspects of proper engineering practices are beyond the scope of this designer's guide. The designer should consult noise suppression techniques described in technical publications and journals, electronics and electrical engineering text books, and component supplier application notes. Seminars addressing noise suppression techniques are often offered by technical and professional associations as well as component suppliers.

7.1 PC BOARD LAYOUT GUIDELINES

1. Provide an adequate ground.
 - a) In a 2-layer design, provide a ground grid in all unused space around and under components (judiciously near analog components) on both sides of the board and connect in such a manner as to avoid small islands. A grid is preferred over a plane to improve solderability. Typically, the grid is composed of .012 in. traces and .012 in. spaces on a .025 in. grid. Connect each grid to other grids on the same side at several points and to grids on the opposite side through the board at several points. Connect all MDP DGND and AGND pins to the ground grid.
 - b) In a 4-layer design, provide a ground plane covering the entire board. Connect all MDP DGND and AGND pins to the ground plane at a single point.
2. As a general rule, route digital signals on the component side of the PCB and the analog signals on the solder side. The sides may be reversed to match particular OEM requirements. Route the digital traces perpendicular to the analog traces to minimize signal cross coupling.
3. Route the MDP signals to provide maximum isolation between noise sources and noise sensitive inputs. When layout requirements necessitate routing these signals together, they should be separated by neutral signals. The MDP noise source, neutral, and noise sensitive pins are listed in Table 7-1.
4. All power and ground traces should be at least 0.05 inch wide.
5. Keep all traces and component leads connected to crystal input and output pins (e.g., XTLI and XTLO) short in order to reduce induced noise levels and minimize any stray capacitance that could affect the crystal oscillator. Keep the XTLO trace extremely short with no bends greater than 45 degrees and containing no vias since the XTLO pin is connected to a fast rise time, high current driver.
6. Connect crystal can(s) to ground.
7. Locate the MDP and all supporting analog circuitry, including the data access arrangement, on the same area of the PCB.
8. Locate the analog components close to and on the side of board containing the TXA1, TXA2, and RIN signals.
9. Avoid placing noisy components and traces near TXA1, TXA2, RIN, VC, and VREF lines.
10. Locate receivers and drivers for DTE EIA-232 serial interface signals close to the connectors and away from traces carrying high frequency clocks in order to avoid/minimize the addition of noise suppression components (i.e., chokes and capacitors) for each line.
11. Route MDP interconnect signals (e.g., MSCLK to IA1CLK or MSTROBE to SA1CLK) directly to the interfacing by the shortest possible route avoiding all analog components.
12. Provide an RC network on the VAA supply in the immediate proximity of the AVAA pin to filter out high frequency noise above 115 kHz. A tantalum capacitor is recommended (especially in a 2-layer board design) for improved noise immunity with a current limiting series resistor or inductor to the VAA supply which meets the RC filter frequency requirements.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

13. Provide a 0.1 μ F ceramic decoupling capacitor to ground between the high frequency filter and the AVAA pin.
14. Provide a 0.1 μ F ceramic decoupling capacitor to ground between the VCC supply and the VDD pins.

Table 7-1. Modem Pin Noise Characteristics

Device	Function	Noise Source	Neutral	Noise Sensitive

7.2 ELECTROMAGNETIC INTERFERENCE (EMI) CONSIDERATIONS

The following guidelines are offered to specifically help minimize EMI generation. Some of these guidelines are redundant with, or similar to, the general guidelines but are mentioned again to reinforce their importance.

In order to minimize the contribution of the modem-based design to EMI, the designer must understand the major sources of EMI and how to reduce them to acceptable levels.

These guidelines assume a microcontroller unit (MCU) is connected to the MDP.

Crystal Circuit

1. Place the crystal and related components as close as possible to the MCU and MDP devices, and in particular, the XTLI and XTLO pins.
2. For MCU and MDP devices that do not have an internal series resistor in the crystal circuit, place a 100-ohm (typical) resistor between the XTLO pin and the crystal/capacitor node.
3. Connect crystal capacitor ground connections directly to GND pin on the MCU and MDP devices. Do not use common ground plane or ground trace to route the capacitor GND pin to the corresponding MCU or MDP GND pin.

Digital Components

1. Place digital components close together in order to minimize signal trace length.
2. Use decoupling capacitors (0.1 μ F) on each digital component.
3. Place one large 10 μ F tantalum capacitor between power and ground near digital components.

Circuit Traces

1. Avoid right angle (90 degree) turns on high frequency traces. Use smoothed radiuses or 45 degree corners.
2. Minimize the number of through-hole connections (feedthroughs) on traces carrying high frequency signals.
3. Keep all signal traces away from crystal circuits.
4. Keep digital signals, EIA/TIA-232 signals, and DAA signals separated from each other.
5. Provide a good ground plane or grid. In some cases, a multilayer board may be required with full layers for ground and power distribution.
6. Eliminate ground loops, which are unexpected current return paths to the power source.
7. Locate high frequency circuits in a separate area to minimize capacitive coupling to other circuits.
8. Locate cables and connectors so as to avoid coupling from high frequency circuits.
9. Lay out the highest frequency signal traces next to the ground grid.
10. If a multilayer board design is used, make no cuts in the ground or power planes and be sure the ground plane covers all traces.
11. On 2-layer boards with no ground grid, provide a shadow ground trace on the opposite side of the board to traces carrying high frequency signals. This will be effective as a high frequency ground return if it is three times the width of the signal traces.
12. Distribute high frequency signals continuously on a single trace rather than several traces radiating from one point.

Signal Conditioning

1. Keep traces carrying high frequency signals as short as possible.
2. Condition high frequency, long trace, and digital signals by inserting a series resistor (300 ohm typical) in the signal source.
3. Conditioning the \sim READ signal alone may provide adequate EMI reduction.
4. Conditioning the address or data lines might also be necessary.

EIA/TIA-232 Interface Components

1. Place components close to each other and close to the EIA/TIA-232 interface cable connector.
2. Connect power and ground for all RS-232 components to the power and ground source points via separate power and ground traces that are not connected to the digital power and ground "except" at these source points. Power and ground source points are the board input pins or a regulator output if used.
3. Connect RS-232 cable signal ground wire to the ground source point.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

4. Connect the EIA/TIA-232 cable shield ground to the ground source point.

Telephone and Local Hand Set Interface

1. Place common mode chokes in series with Tip and Ring for each connector.
2. Decouple the telephone line cables at the telephone line jacks. Typically, use a combination of series inductors, common mode chokes, and shunt capacitors. Methods to decouple telephone lines are similar to decoupling power lines, however, telephone line decoupling may be more difficult and deserves additional attention. A commonly used design aid is to place footprints for these components and populate as necessary during performance/EMI testing and certification.
3. Place high voltage filter capacitors (.001 μ F @ 1KV) from Tip and Ring to Ground.

Stand Alone Modem Chassis

1. Use a metal enclosure.
2. If a plastic enclosure is required, internal metal foil lining the enclosure or conductive spray applied to the top and bottom covers may reduce emissions.

Power and Ground

1. Keep the current paths of separate board functions isolated, thereby reducing the current's travel distance. Separate board functions are: host interface, display, digital (SRAM, EPROM, MCU, MDP), and DAA. Power and ground for each of these functions should be separate islands connected together at the power and ground source points only.
2. Do not place ground or voltage planes beneath the telephone line side of the Tip and Ring chokes.
3. Decouple power from ground with decoupling capacitors as close to the MDP device power pins as possible.
4. Decouple the power cord at the power cord interface with decoupling capacitors. Methods to decouple power lines are similar to decoupling telephone lines.

Optional Configurations

Because fixed requirements of a design may alter EMI performance, guidelines that work in one case may deliver little or no performance enhancement in another. Initial board design should, therefore, include flexibility to allow evaluation of optional configurations. These optional configurations may include:

1. Chokes in Tip and Ring lines replaced with jumper wires as a cost reduction if the design has sufficient EMI margin.
2. Various grounding areas connected by tie points (these tie points can be short jumper wires, solder bridges between close traces, etc.).
3. EIA/TIA-232 cable ground wire or cable shielding connected on the board or floated.
4. Two designs in parallel with one based on a two layer board and the other based on a four layer board. During the evaluation phase, better performance of one design over another may result in quicker time to market.

7.3 CRYSTAL SPECIFICATIONS

Recommended crystal specifications are listed in Table 7-2 (28.224 MHz) and Table 7-3 (56.448 MHz).

Table 7-2. Crystal Specifications - 28.224 MHz

Figure 7-5. Package Dimensions - 100-Pin PQFP

8. T.30 IMPLEMENTATION

8.1 GENERAL

ITU-T Recommendation T.30 details procedures for facsimile transmission over the PSTN. This standard describes how to initiate, complete, and end a fax transmission. This section describes methods to set up host software to implement T.30 with the MDP.

A basic block diagram of a Group 3 facsimile machine is shown in Figure 8-1. The MDP performs the modulation/demodulation process. The fax machine manufacturer must implement the interface between the modem (T.30), the data compression/decompression (T.4), and the interface to the scanner and printer.

There are five phases (A-E) to the T.30 facsimile protocol. Phase A is the call setup, in which both facsimile machines connect to the line. Phase B is a pre-message procedure which consists of identification and command sections. The actual high speed message transmission occurs during Phase C. This is followed by the post-message procedure or Phase D. Both facsimile machines release the line in Phase E.

Figure 8-2 illustrates a typical Group 3 facsimile procedure. This example on T.30 describes a facsimile call where the calling unit (originate) transmits a documents to a called unit (answer). Phase E is not included in this example since it is the call release and both ends hang up.

Figure 8-3 through Figure 8-7 illustrate how to originate a fax call. Figure 8-8 through Figure 8-13 illustrate how to answer a fax call. Figure 8-14 through Figure 8-19 illustrate subroutines for originating or answering a fax call.

8.1.1 Phase A

T.30 specifies that call establishment can be realized one of four ways. The four methods of call establishment are: manual-to-manual, manual-to-automatic, automatic-to-manual, and automatic-to-automatic. Manual corresponds to operator or human intervention while automatic means machine only. The explanation that follows describes an automatic-to-automatic example.

After dialing, the calling unit, or originating fax, first transmits a calling tone (CNG) to indicate it is a non-speech terminal. The called unit, or answering fax, then responds with a called station ID (CED). The end of Phase A is signified after the called unit sends a 2100 Hz (CED) tone and the calling unit has detected this tone. Some facsimile manufacturers do not configure the MDP to detect these tones. In this case, the MDP looks for the preamble of flags (see phase B).

8.1.2 Phase B

The pre-message procedure consists of the following handshake. The answering fax machine sends an identification signal and the originating machine responds with a command signal. A training check is sent at a high speed and the receiving machine informs the transmitting machine if the training check was successful. This usually occurs at V.21 300 bps Frequency Shift Keying (FSK) modulation in HDLC format.

HDLC stands for High Level Data Link Control. It is a standard procedure used for data communications. HDLC is a bit-oriented protocol (normally used in synchronous communications) that defines how the data being sent over the data link is organized and arranged.

When using the HDLC protocol, the data is transmitted via frames. These frames organize the data into a format specified by an ISO (International Standards Organization) standard that enables the transmitting and receiving station to synchronize with each other. Figure 8-20 illustrates the HDLC frame structure used for the facsimile protocol.

The preamble is a series of HDLC Flags for one second $\pm 15\%$. The purpose of the 7E flags is to condition the line. The flag sequence defines the beginning and ending of a frame. The address field is required to provide identification for multi-point addressing. For PSTN the format is 11111111. The control field's purpose is to provide the capability of encoding the commands and responses. The format is 1100X000 (X = 0 non-final frame; X = 1 final frame).

The HDLC information field provides the specific information for the control and message interchange between the two stations. In the fax protocol the format for the information field consists of two parts, the Facsimile Control Field (FCF) and the Facsimile Information Field (FIF).

The FCF contains information regarding the type of information being exchanged and the position in the overall sequence. The acronyms, functions, and format for FCF commands are defined in the T.30 Recommendation. The FIF contains additional information which further clarifies the facsimile procedure. Some examples of information communicated with the FIF are: group capability, data rate, vertical resolution, coding scheme, recording width, recording length, and minimum scan line time.

The Frame Check Sequence (FCS) follows the FIF. The MDP automatically generate the FCS or Cyclic Redundancy Check (CRC). The frame ends with an ending 7E flag. It is recommended that more than one ending flag be transmitted.

After the MDP has been configured for FSK, the Digital Identification Signal (DIS) is transmitted by the called unit. The DIS informs the calling unit about the called unit's capabilities such as group capability (G1, G2, G3), data rate, vertical resolution,

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

coding scheme (Modified Huffman, Modified Read), recording width, recording length, and minimum scan line time. The calling unit then responds with a Digital Command Signal (DCS) which informs the called unit which options are chosen to complete this facsimile call.

After the DCS is transmitted, both the calling unit and the called unit set up for the high speed configuration that was chosen and transmitted via the DCS. A Training Check (TCF) is transmitted by the calling unit to verify training and give an indication of channel acceptability for the selected data rate. The TCF consists of a series of zeros for 1.5 seconds $\pm 10\%$. Since the called unit knows it will be receiving 1.5 seconds of zeros, the host can make a decision whether the line is good enough at the chosen data rate or fallback to a slower speed.

After completing the TCF, the calling unit and the called unit re-configure for FSK, HDLC format. The called unit then transmits either a Confirmation to Receive (CFR) or a Failure To Train (FTT). The CFR is a response informing the calling unit of a successful pre-message procedure completion. A FTT informs the calling unit that the training signal was rejected and requests re-training. If a FTT is received by the calling unit, the fax protocol jumps back to the transition of DCS and continues until finally a CFR is received or the calling unit host decides to terminate the call.

8.1.3 Phase C

Phase C occurs after both facsimile machines have set up for the high speed configuration that was decided upon in phase B. The T.30 Error Correction Mode is addressed in a following section. The high speed message information is usually compressed data using a Modified Huffman (MH) or Modified Read (MR) algorithm. The host processor must perform the MH or MR compression before loading the data into the MDP. On the receive end, the host processor must perform the MH or MR decompression.

The start of phase C is denoted by an End Of Line (EOL) 8-bit code. The data follows this first EOL character until the end of the line. Another EOL character is transmitted to indicate a new line. A minimum transmission time of a total coded scan line is measured from the beginning of the EOL to the beginning of the following EOL. If the transmitted data requires less time than the minimum transmission time, fill bits must be transmitted. Six consecutive EOL character constitute a Return To Control (RTC) command meaning end of document transmission. Figure 8-21 illustrates the phase C format.

8.1.4 Phase D

The post-message phase D procedure uses FSK and HDLC format. The calling station will typically send an End Of Message (EOM) signal. This FCF command (EOM) informs the called station that this is the end of the page and return to Phase B. A Multi-Page Signaling (MPS) or End Of Procedure (EOP) signal may be sent instead of EOM. The MPS signal informs the called unit that there are more pages in this facsimile transmission. EOP signals the end of the facsimile transmission. Procedure Interrupt-EOM (PRI-EOM), Procedure Interrupt-MPS (PRI-MPS), and Procedure Interrupt-EOP (PRI-EOP) indicate the same as EOM, MPS, and EOP, respectively, with the additional optional capability of requesting operator intervention. If operator intervention is required, further facsimile procedures commence at the beginning of phase B.

The called station might respond to an EOM, MPS, or EOP signal with a Message Confirmation (MCF) command. This FCF command indicates to the calling unit that the complete message was received. One of the following FCF commands may be sent instead of the MCF: Re-Train Positive (RTP), Re-Train Negative (RTN), Procedure Interrupt Positive (PIP), or Procedure Interrupt Negative (PIN). RTP indicates that a complete message has been received and that additional messages may follow after retransmission of TCF and CFR. RTN indicates that the previous message has not been satisfactorily received, however, further receptions may be possible provided there is a retransmission of TCF and CFR. PIP and PIN indicate that the previous message was received satisfactorily or not satisfactorily, respectively, and operator intervention is required for further transmissions.

8.1.5 Phase E

Call Release, or phase E, occurs after the last post-message signal of the procedure or under certain conditions such as a time-out, procedural interrupt, or a Disconnect (DCN) command.

The DCN command indicates the initiation of phase E. This command requires no response.

8.2 ERROR CORRECTION MODE

8.2.1 General

The revised T.30 contains an Error Correction Mode (ECM) option. The ECM allows the phase C portion of the facsimile transmission to be encoded in a HDLC framing format using a specified number of bits in the information field. The transmitted high speed message is broken up into a number of frames identified by frame numbers. If an error is detected during reception of the message, the called station records the frame number. After all the frames in the message has been received, the called station transmits the frame numbers that were received in error. The calling station then re-transmits only those frames in error. This continues until the entire message is received error free or the calling station decides not to transmit any more frames.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

The error detection is performed by comparing the CRC or FCS. Using ECM, the fax data rate can be as fast as 14400 bps, therefore, the host microprocessor may not be able to keep up if implementing HDLC without the use of a serial I/O device.

8.2.2 ECM Frame Structure

In Error Correction Mode, one frame of facsimile data consists of 256 or 64 octets of data. Each page may contain 1 to 256 frames. Also, 1 to 256 pages may be transmitted. The ECM frame structure is illustrated in Figure 8-22. Following the high speed training sequence, the flag, address field, and control field is transmitted. In ECM, Flag = 7E, Address = FF, and Control = B0. The Facsimile Control Field for the Facsimile Coded Data block (FCD) is 60. The frame number follows the FCF for FCD, followed by the facsimile data. Pad bits such as EOL, Tag, and Align bits follow the facsimile data. Finally, the FCS check and the ending flag is transmitted.

After 256 frames, a Return Control for Partial page (RCP) block is transmitted three times. The RCP block consists of the same Flag, Address Field, and Control field followed by the FCF for RCP. The FCS immediately follows with the ending flag. After the third RCP, a maximum of 50 ms of flags are transmitted.

An ECM message protocol example is shown in Figure 8-23. The bold arrows are high speed transmissions and the other arrows are FSK transmissions. The example is self-explanatory. If more information is needed, refer to the T.30 ECM specification.

In this paragraph, the Q refers to the NULL, EOP, MPS, or EOM Facsimile Control Field commands. The Partial Page Signals (PPS-Q) and Partial Page Request (PPR) frame structures are shown in Figure 8-24. The PPS-Q frame begins with the same Flag, Address field, and Control field. Two FCF commands follow. The first FCF transmitted is to indicate PPS. The second FCF is either NULL, EOP, MPS, or EOM. The page count followed by the block count, followed by the total number of frames in the block are transmitted next. The FCS and ending flag are finally transmitted.

The PPR frame structure also begins with the same Flag, Address, and Control field. The FCF for PPR is the next octet. The FIF consists of 256 or 64 bits depending on how many frames were transmitted. The contents of FIF is either a 0 or a 1. The bit number corresponds to the frame number and a 0 indicates the frames was received correctly and a 1 indicates an incorrect frame was received.

8.3 SIGNAL RECOGNITION ALGORITHM

A method of determining whether a high speed message or FSK handshaking is being received by the MDP is necessary when implementing the T.30 recommendation. When the calling unit transmitter and called unit receiver configure for V.29 or V.27 ter, sometimes the high speed message may not be received (typically due to a noisy line). In this case, the calling unit transmitter will try to send the message up to three times before re-negotiating in FSK signaling. The called unit receiver must, therefore, be able to distinguish between a high speed message and FSK handshaking.

The algorithm shown in Figure 8-25 can be used to perform the signal recognition. The use of the P2DET and PNDDET status bits may also be incorporated for qualifying high speed PSK carrier.

High speed PSK reception in high noise environments can be optimized by setting the RTH bits so that the level of the noise is below the MDP's receiver threshold. This can be accomplished by measuring the received signal level via the AGC gain word RAM access while receiving the V.21 channel 2 carrier. Then, after configuring to a high speed configuration, RTH should be set to a value which will provide a threshold range centered around the expected receive level.

9. V.8 OPERATION CONSIDERATIONS

The host can access several registers in RAM to control and monitor V.8 operation (see Section 4). There are five control registers (Table 9-1) and three status registers (Table 9-2). The host also has access to 13 registers, which contain the configuration (CONF) codes associated with the 13 modes of operation (Table 9-3).

To enter V.8 mode, load the interface memory CONF register (Table 3-1) with AA and then set the NEWC bit.

9.1 V.8 ORIGINATING MODEM OPERATING PROCEDURE

Once in the V.8 mode, set DTR to initiate the V.8 handshake.

In originate mode, the transmitter is set up to transmit Silence by default. (Optionally, CI may be sent if the host sets bit 304h:2.) The receiver is set up to detect ANS and ANSam. The data pump sets bit 301h:5 when ANS is detected and sets bit 302h:3 when ANSam is detected.

9.1.1 Originating Without CI Option (Default)

Once ANSam is detected, the transmitter waits a silence period before transmitting CM. The silence period is 500 ms if no phase reversals are detected in ANSam, otherwise the silence period is 1 second. The CM sequence consists of a Preamble, followed by a SYNC octet, a Data Call Function Category octet, at least one modulation mode octet, an optional protocol octet, and an optional GSTN octet. The 16-byte transmit buffer, located at address 32Dh, is loaded with the CM sequence once ANSam is detected.

The number of modulation mode octets transmitted is a function of the bit settings in control addresses 306h to 308h (Table 9-1). For example, if no modulation bits are set in addresses 307h or 308h, then only one modulation octet is sent (modn0). On the other hand, if bits are set in address 307h, but not in address 308h, then modn0 and modn1 are sent. Only when address 308h contains non-zero modulation bits will all three modulation octets be sent.

The protocol octet is transmitted if bit 305h:0 is set. The 3-bit protocol field is located in bits 305h:7-5. The default protocol bits are set to indicate LAPM availability. The GSTN octet is sent if bit 304h:4 is set. The GSTN octet will be sent indicating cellular access if bit 305h:2 is set.

CM transmission continues until JM is detected. When JM is detected, the current CM octet is completed and then CJ gets appended to the transmitted data stream. A 75 ms silence period follows CJ transmission and the CONF register is updated to the "Modulation Mode" indexed by the highest common modulation mode in JM (Table 9-3).

If no modulation modes are common, the CONF register changes to AFh, the "V.8 Cleardown" mode.

9.1.2 Originating With CI Option

Once DTR transitions on, the transmitter is silent for 400 ms before the CI sequence is transmitted. CI is sent with a regular cadence of 1 second on and 1 second off. The on and off times are accessible via memory access (Section 4, Functions 89). In particular, the on time counter, MaxFrameByteCount, is located at 31Ch. This counter is a "byte" counter and defaults to 30 bytes for CI transmission. (Note that the MaxFrameByteCount should not be less than 9 { = 3 frames } if the minimum three frames of CI is desired.) If this location is negative (i.e., MSB = 1), then there is no cadence applied to the transmitted V.8 frame.

Note: MaxFrameByteCount = FFh when transmitting CM and JM.

The CI cadence will continue until ANSam is detected and the minimum three CI frames have been transmitted. Upon detection of ANSam, CM is sent in the manner described in Section 9.1.1.

9.2 V.8 ANSWERING MODEM OPERATING PROCEDURE

If configured as the V.8 answer modem, the transmitter will transmit ANSam. The receiver will detect V.8 frames CI, CM, and CJ. Bits 301h:3-1 hold the status of CM, CI, and CJ detection (Table 9-2).

When CM is detected, a JM frame is constructed using parameters from CM.

The JM sequence starts with the 10 ONES preamble followed by the synchronization octet. Next comes the call function. If the received CM octet contains the same call function as the answer modem's "preferred" call function, then the same call function that was received in CM is also sent in JM.

If the CM octet contains a different call function than the "preferred" call function, then the CallFunctionAllowed register (address 32Ah) is consulted. The host can set up the CallFunctionAllowed register to indicate the call functions that it allows. It is a bit-mapped register where bit k is set if call function 2k is to be allowed. If the call function received in CM does not match any allowable call functions, then the preferred call function is returned with all modulation bits set to zero. On the other hand, if the call function is allowed, the answer modem will respond with the same call function as that received in CM.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

JM will contain all the necessary modulation octets needed to reflect the jointly common modulation modes available at the answer modem and received in the CM sequence. However, if bit 305h:1 is set, then JM will contain the minimum number of modulation octets needed to convey the highest common mode. If no modulation modes are common, then the JM frame will send all modulation octets with none of the modulation bits set.

The protocol octet is sent only if the received CM contained a protocol octet AND control bit 305h:0 is set. The GSTN octet is sent if control bit 304h:4 is set OR if the received CM contained a GSTN octet. The GSTN octet will be sent indicating cellular access if control bit 305h:2 is set.

314	V.21	A0

Notes:

- See CONF codes in Table 3-1.
- Default value assumes V.23 answer mode; change to A1 for V.23 originate mode (see CONF bits in Table 3-1).

9.3 V.8 AND AUTOMODE

The MDP offers an automode option for connecting to the large existing base of non-V.34 modems. By setting AUTO = 1 and DATA = 0 from the V.8 configuration (CONF = AA), the "V.32 bis automode" method of automoding will be performed as well as the V.8 method (Table 9-4).

Table 9-4. Automode Parameters

CONF	AUTO	DATA	Result
7Xh (V.32 bis/V.32 modes)	1	0	Automodes from V.32 bis/V.32 to V.22 bis, Bell 212A, V.21, V.23, or Bell 103.
7Xh (V.32 bis/V.32 modes)	0	1	V.32 bis only.
AAh (V.8 mode)*	1	0	Automodes from V.8 to V.90, K56flex, V.34, V.32 bis, Bell 212A, V.22 bis, V.21, V.23, or Bell 103.
AAh (V.8 mode)	0	1	V.8 (V.90, K56flex, or V.34) or V.32 bis.

* Most common mode.

9.4 HANDSHAKE MONITORING

9.4.1 V.8 Octet Monitoring

During the V.8 (Phase 1) procedure the received V.8 octets can be read from the interface memory RBUFFER register by clearing bit 305h:3 in the V.8 host control bits. The procedure is the same as accessing receive data during normal data mode.

Handshake Phase Monitoring

During the V.8/V.34 handshake, the secondary channel data buffers display the “state” of the receiver (SECRXB) and the transmitter (SECTXB). Bits 5, 6 and 7 of these buffers indicate the phase of the handshake (Table 9-5 and Table 9-6).

Using the New Status (NEWS) function, an interrupt can be generated whenever a change occurs to SECRXB and SECTXB. The NEWS masks for these locations are 370h and 371h, respectively. For a full description, refer to Section 4.

Table 9-5. Receiver Handshake Phase and States

10. V.8bis

10.1 V.8bis TRANSMITTER

V.8bis tones can be transmitted from tone mode (CONF = 8Xh), speakerphone mode (CONF = ACh), or V.21 mode (CONF = A0h with V21S = 1). CEQ should be 0. The V8bis tones are sent in the same manner as DTMF tones, i.e., write the codeword into TBUFFER when TDBE=1.

The codewords for V.8bis are described in Table 10-1.

Table 10-1. V.8 bis Codewords

V.8bis Codeword (Hex)	V.8bis Signal	Segment 1 Dual Tones (Hz)	Segment 1 Power level (dBm)	Segment 2 Single Tones (Hz)	Segment 2 Power level (dBm)
20	MR _e	1375 + 2002	-23.5	650	-23.5
21	MR _d	1375 + 2002	-10	1150	-10
22	CR _e	1375 + 2002	-23.5	400	-23.5
23	CR _d	1375 + 2002	-10	900	-10
24	ES _i	1375 + 2002	-10	980 *	-10
28	MR _e	1375 + 2002	-10	650	-10
2A	CR _e	1375 + 2002	-10	400	-10
30	**	1529 + 2225	-23.5	650	-23.5
31	MR _d	1529 + 2225	-10	1150	-10
32	**	1529 + 2225	-23.5	400	-23.5
33	CR _d	1529 + 2225	-10	1900	-10
34	ES _r	1529 + 2225	-10	1650 *	-10
38	**	1529 + 2225	-10	650	-10
3A	**	1529 + 2225	-10	400	-10
Notes: * The 1650 Hz and 980 Hz single tones are V.21 MARK frequencies for the high and low channels, respectively. Therefore, it would be generated by setting DTR immediately after writing 34h or 24h into TBUFFER. If in answer mode, set NV25 =1 to prevent answer tone from being sent instead of MARK. ** These signals are available, but are currently undefined by V.8bis.					

10.2 V.8bis RECEIVER

The V.8bis detector is enabled by setting bit 439h:0 = 1 and setting NEWC from dial modes (CONF = 8Xh), speakerphone mode (CONF = ACh), or V.21 mode (CONF = A0h with V21S = 1). (When in tone mode, the “talk-mode tone detectors” are unavailable when running the V.8bis receiver.)

When a valid V.8bis signal is received, the corresponding codeword appears in the V.8bis RX buffer (16h). Also, bit 7 of the V.8bis Rx buffer (16h:7) indicates that a dual tone has been detected. A value of E0h means that a valid Segment 1 (dual tone) has been received and a single tone is being detected.

This page is intentionally blank.

11. ADPCM VOICE COMPRESSION AND DECOMPRESSION

ADPCM compression (Rx-coding) of received, ADC digitized voice may be selected to minimize the memory required for message storage. Silence detection and deletion may also be selected to further reduce the memory storage requirements.

ADPCM decompression (Tx-decoding) of stored/recorded compressed voice may be selected in order to either playback or transmit messages. Silence interpolation may be enabled to interpolate any silence deleted during reception.

Data flow through the Rx-coder and Tx-decoder are shown in Figure 11-1 and Figure 11-2, respectively.

11.1 ADPCM RECEIVER (RX-CODER)

11.1.1 Mode Selection

ADPCM Rx-coding is selected when Coder Enable (CDEN) is set, CONF = ACh, and Receive Voice (RXV) is set. (See Table 11-1.)

Squelching the transmitter output by setting the TXSQ bit will prevent the TXA1 and TXA2 noise floor from being coupled back into the RXA input when receiving voice samples in (either pass-through or ADPCM voice mode).

11.1.2 Operation

When Rx-coding is selected, received analog voice from the RXA input is sampled, converted to digital, digitally scaled, compressed (coded), then passed to the 16-bit Voice Receive Buffer (VBUFR) where the speech samples can be read by the host (Figure 11-1). Typical receive ADPCM voice mode operation is illustrated in Figure 11-3.

The host must select 2, 3, or 4 bits per sample compression with the Coder No. of Bits (CODBITS). With 2, 3, or 4 bits per sample at the 7.2k Hz default programmable sample rate, the 16-bit coder output words are provided at 14.4k, 21.6k, or 28.8k bps (900, 1350, or 1800 16-bit words per second), respectively. The specific application will dictate a higher bits/sample rate for best speech quality or a lower bits/sample rate for minimum storage requirements.

The Rx-coder writes 16-bit coded words to output register VBUFR then sets status bit RDBF. The IRQ output may be enabled using the RDBIE bit to interrupt the host whenever the RDBF bit sets to indicate that VBUFR is full.

Receive FIFO Operation

The receiver FIFO is always enabled, similar to data mode, to allow reading in bursts if desired. Always read from RBUFFER with the data coming in low-high order. The host must first read the status bits before reading the data. The low byte is ready to be read when PE is set and the high byte is ready to be read when FE is set. The first voice sample is ready when both SYNCD and PE are set.

11.2 ADPCM TRANSMITTER (TX-DECODER)

11.2.1 Mode Selection

ADPCM Tx-decoding is selected when Decoder Enable (DCDEN) is set, CONF = ACh, and Transmit Voice (TXV) is set. (See Table 11-1.)

11.2.2 Operation

When TX-decoding is selected, compressed digital voice samples (coded words) received from the host through the 16-bit Voice Transmit Buffer (VBUFT) are decompressed (decoded), digitally scaled, converted to analog, then routed to the TXA1 and TXA2 outputs (Figure 11-2). Typical transmit ADPCM voice mode operation is illustrated in Figure 11-4.

The host must select 2, 3, or 4 bits per sample decompression with the Decoder No. of Bits (DECBITS).

The host supplies the decoder with the 16-bit coder output words by writing to VBUFT when TDBE is set.

Transmit FIFO Operation

Set FIFO = 1 to enable the transmit FIFO. Reset TEOF = 0. Write the low byte to TBUFFER. Set TEOF = 1 and then send the first high byte to TBUFFER. This will sync the host data stream and the data pump. Continue transmitting the 16-bit words in low-high order via TBUFFER while TXFNF = 1.

Table 11-1. ADPCM Voice Mode Selection

CONF	RXV	TXV	CDEN	DCDEN	Mode
*	0	1	0	0	Tx Pass-through Voice Mode
*	0	1	0	1	Tx ADPCM Voice Mode
*	1	0	0	0	Rx Pass-through Voice Mode
*	1	0	1	0	Rx ADPCM Voice Mode

NOTES:
* = ACh, 80h, 81h, 83h, or 86h.

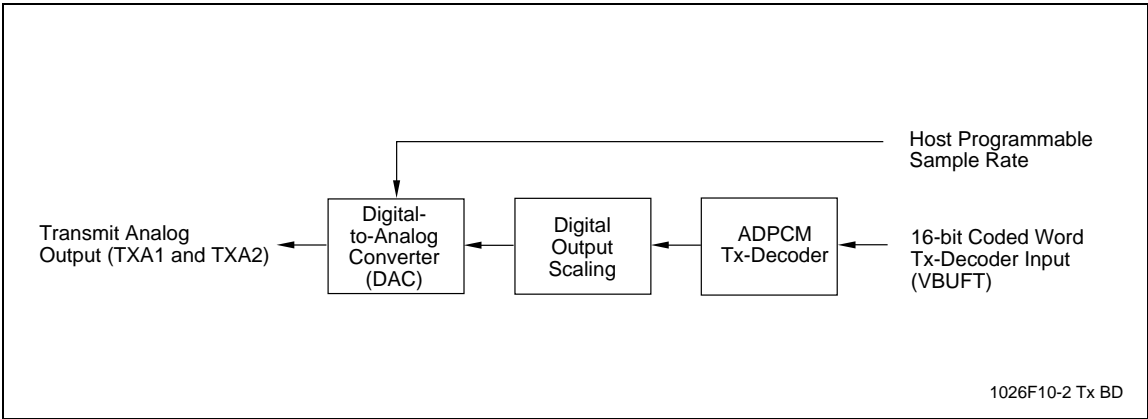

Figure 11-2. ADPCM Tx-Decoder

Figure 11-3. Rx-Coder Operation

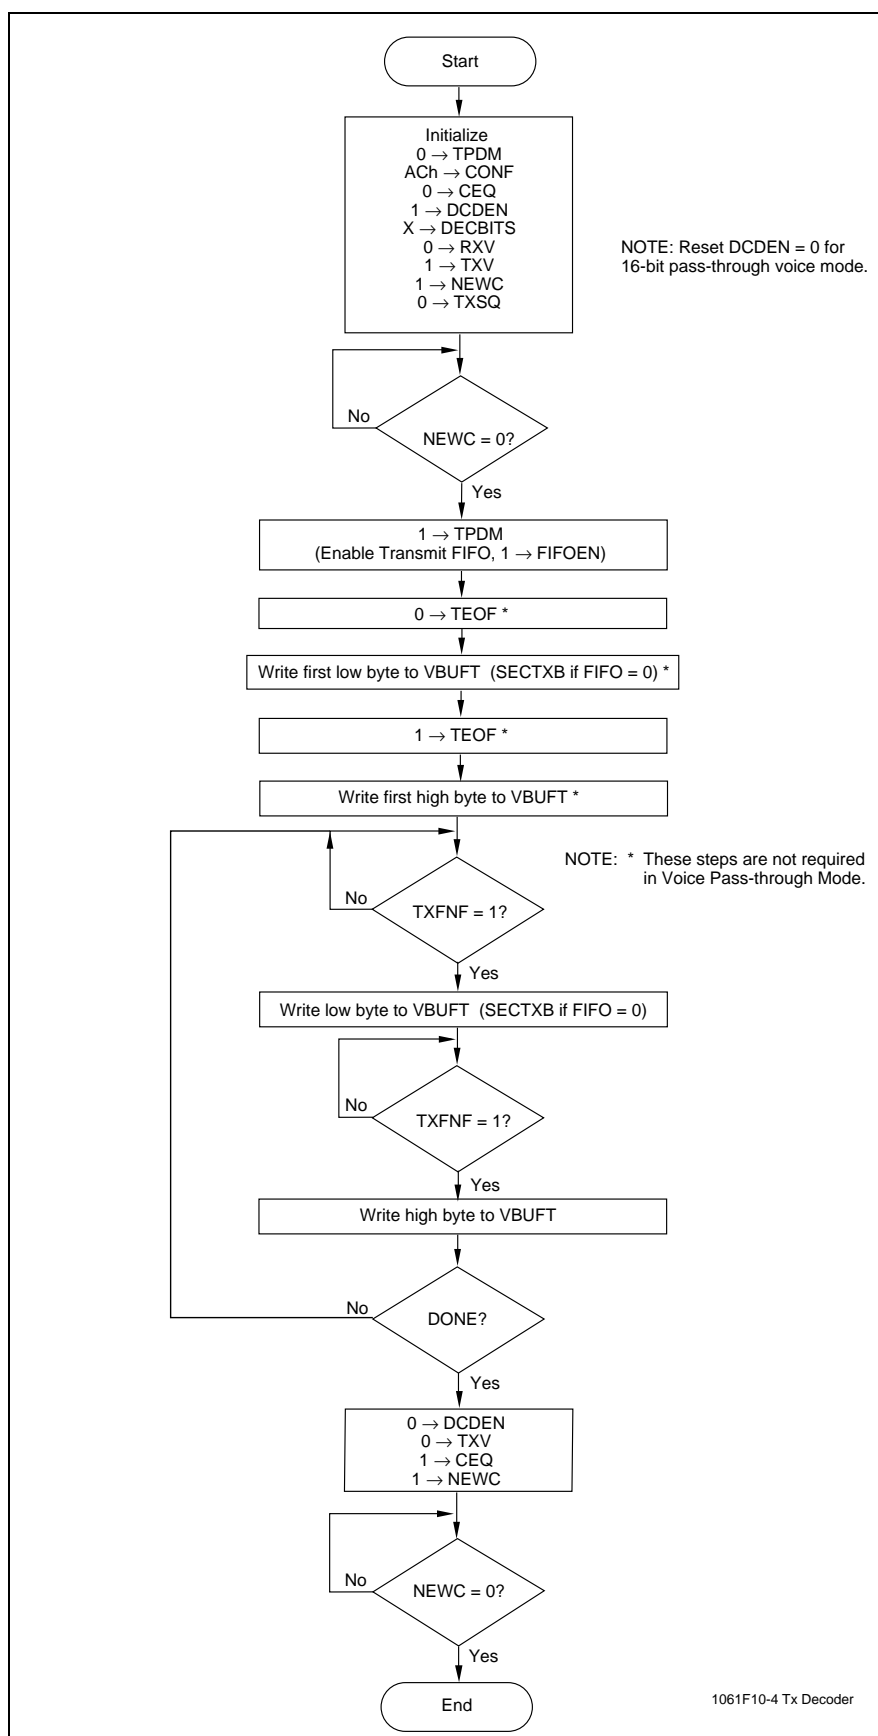

Figure 11-4. Tx-Decoder Operation

11.3 VOICE AGC

An optional AGC function is included in the voice receiver (compressed and uncompressed). Voice AGC is enabled or disabled by setting or resetting the VAGC bit [04h:2 (shared with NRZIE)].

The AGC is updated on a 28-sample "voice frame" basis. The average input sample (AverageENG) is compared to a voice threshold (VTHRESH) to determine if there is enough energy to perform the automatic gain control (AGC). When the average energy is below this threshold, the input samples are not AGC'ed. When the energy is above the threshold, the Gain is updated and the Gain is applied to the next voice frame. Gain is only updated when the energy is above VTHRESH and only once per voice frame. Furthermore, Gain is limited to the maximum voice gain (VMAXG).

11.3.1 Voice AGC Parameters

The voice AGC parameters are listed in Table 11-2.

Table 11-2. Voice AGC Parameters

Name	Description	Address (Hex)	Default* (Hex)
VMAXG	Maximum Gain	E63	4000
VAGCREF	AGC Reference Level	E62	0800
VTHRESH	AGC Energy Threshold	E65	0000
VSRATE0	Slew Rate 0	F62	4500, then 0300
Alpha	Low Pass Filter Gain	F61	0100
Pole	Low pass Filter Pole	D62	7EFF
VoiceSlewRateCtr	Counter Slew Rate Adjustment	3AE, 3AF	F10
* If bit 1 of register 04 (shared with TOD) is set, then the above voice AGC parameters are not initialized. This allows the host to write in values without having to worry about contentions with the data pump initialization.			

Voice AGC Reference (VAGCREF)

The AGC algorithm adjusts the Gain so that the squared output of the Voice LPF, (LPFOutput)², tends to VAGCREF. The default value of VAGCREF is 0100h corresponding to a recorded level of nearly -16 dBm. By lowering VAGCREF, the recorded volume is lowered.

Slew Rate (VSRATE)

The slew rate parameter controls the rate at which the gain tracks the input signal. The larger the slew rate multiplier, the faster the AGC Gain word tracks the input signal.

The VoiceSlewRateCtr is used to allow the AGC gain word to quickly adjust to the input level at the beginning of the recording and then slow down to a "steady-state" rate thereafter. The counter counts down at the 16-bit data rate and is disabled when the most significant byte is negative. The default VoiceSlewRateCtr value corresponds to two seconds for 4-bit ADPCM recording. So for the first two seconds, the AGC slew rate is 4500h and then it changes to 0300h for the remainder of the recording.

Maximum Gain (VMAXG)

The Gain value is limited to VMAXG. When VMAXG is small, the AGC process works to a lower level of input. Under default conditions, the 4000h value of VMAXG cuts off at -40 dBm. That is, the Gain remains constant (= VMAXG) for input levels below -40 dBm. By lowering VMAXG, lower level signals will receive gain.

Voice Energy Threshold (VTHRESH)

When the average frame value is above VTHRESH, the AGC process runs, otherwise the received samples are recorded without gain. This threshold comparison is intended to prevent the noise floor from being raised during silence periods. This "silence" feature can introduce choppiness if not tuned correctly. As a result, the default value for VTHRESH is zero which, effectively, disables this feature.

Low Pass Filter Output (LPFOutput)

The low pass filter output is a function of the input level and the LPF gain, Alpha. The default value of Alpha, together with the LPF pole value, give a LPF gain of 0 dB. By increasing Alpha, the recorded volume is lowered.

$$\text{AGC Gain Equation: Gain} = \text{Gain} + [(\text{LPFOutput})^2 - \text{VAGCREF}] \text{VSRATE}$$

This page is intentionally blank.

12. VOICE MODE CONFIGURATIONS

12.1 VOICE PATHS

The following describes how to setup the voice mode paths. The Integrated Analog (IA) function has a dual interface: a Modem IA and a Voice IA. The voice transmit and receive paths can be switched through either IA. The speaker output can be from one of three different sources, RIN, mic (MICM or MICV) or MDP DSP. The input can be selected from RIN/TELIN or the Mic. Refer to the voice path figures at the end of this section. **Note:** The voice paths apply to CONF = ACh (Speakerphone mode), TXV = 1 and/or RXV = 1.

The voice block diagram is shown in Figure 12-1.

The transmit voice receiver path is illustrated in Figure 12-2 and the receiver voice path is illustrated in Figure 12-3.

12.1.1 L8771 Voice Operation Differences from L8570 Devices

While the usual voice path control bits in 3E1h and 3E0h are still valid for L8570-based devices, L8771-based devices no longer support these two locations for voice path control. The transmit and receive path diagrams (Figure 12-2 and Figure 12-3) show the old 3E1/3E0h addresses/bits in [] brackets and the new equivalent addresses/bits in { } brackets. These newly described locations are the direct IA control word locations. Addresses 3E1/3E0h on the L8570 devices actually manipulate these IA control words indirectly. The IA control words may be used on both L8570 and L8771 based devices. When using these new addresses, NEWC must not be set, otherwise, the voice path settings may change. This is true for both L8570 and L8771 based devices.

The L8771 voice operation differs in several ways from the L8570-based devices:

- Voice paths selected through new addresses as mentioned above.
- Voice sample rate of 8k has been added.
- New VINIT bit is used to invoke voice operation after TXV, RXV and other voice options are set. VINIT will clear once configuration is complete. VINIT is the "NEWC" of voice mode.
- Voice samples may be 16-bit linear or 8-bit PCM (A-law or u-law)
- ADPCM voice mode operation is supported in CONF mode ACh only. Other voice operations are supported in both CONF modes ACh and 8Xh. The device need not be a speakerphone device for CONF mode ACh to work.
- Voice samples, in modes other than ADPCM voice mode) may be handled through the parallel interface or, optionally, through the serial interface. The serial voice interface allows concurrent voice and data operations. The PLL must be powered and enabled for concurrent voice and data.
- Tone detectors may run at a 7.2 kHz or 8 kHz when the sample rate runs at 8 kHz in CONF mode ACh.

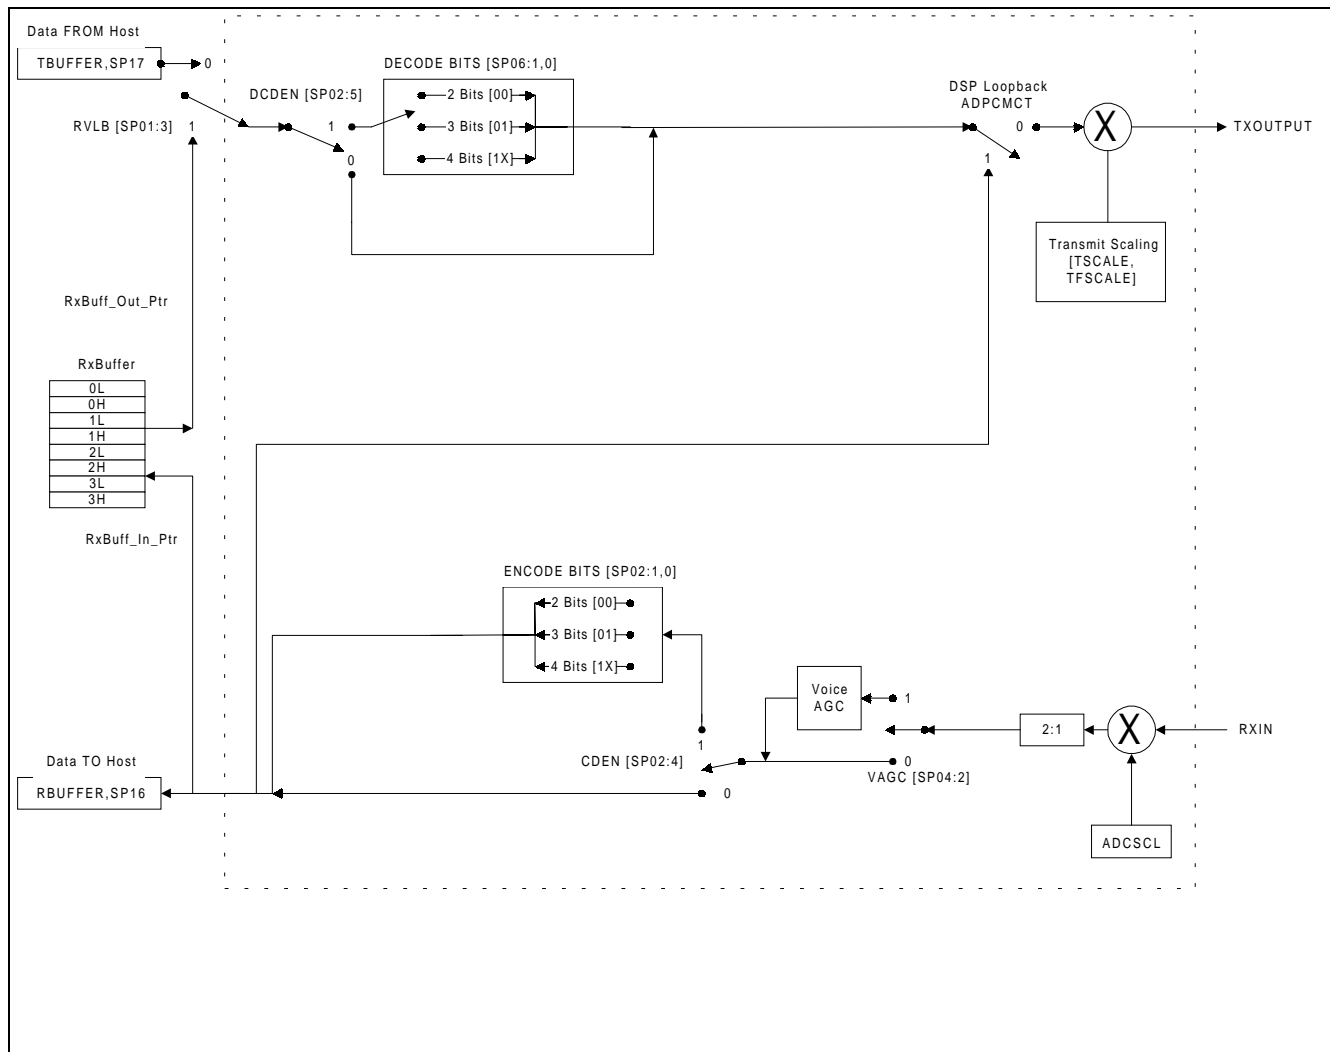

Figure 12-1. Voice Flow Block Diagram

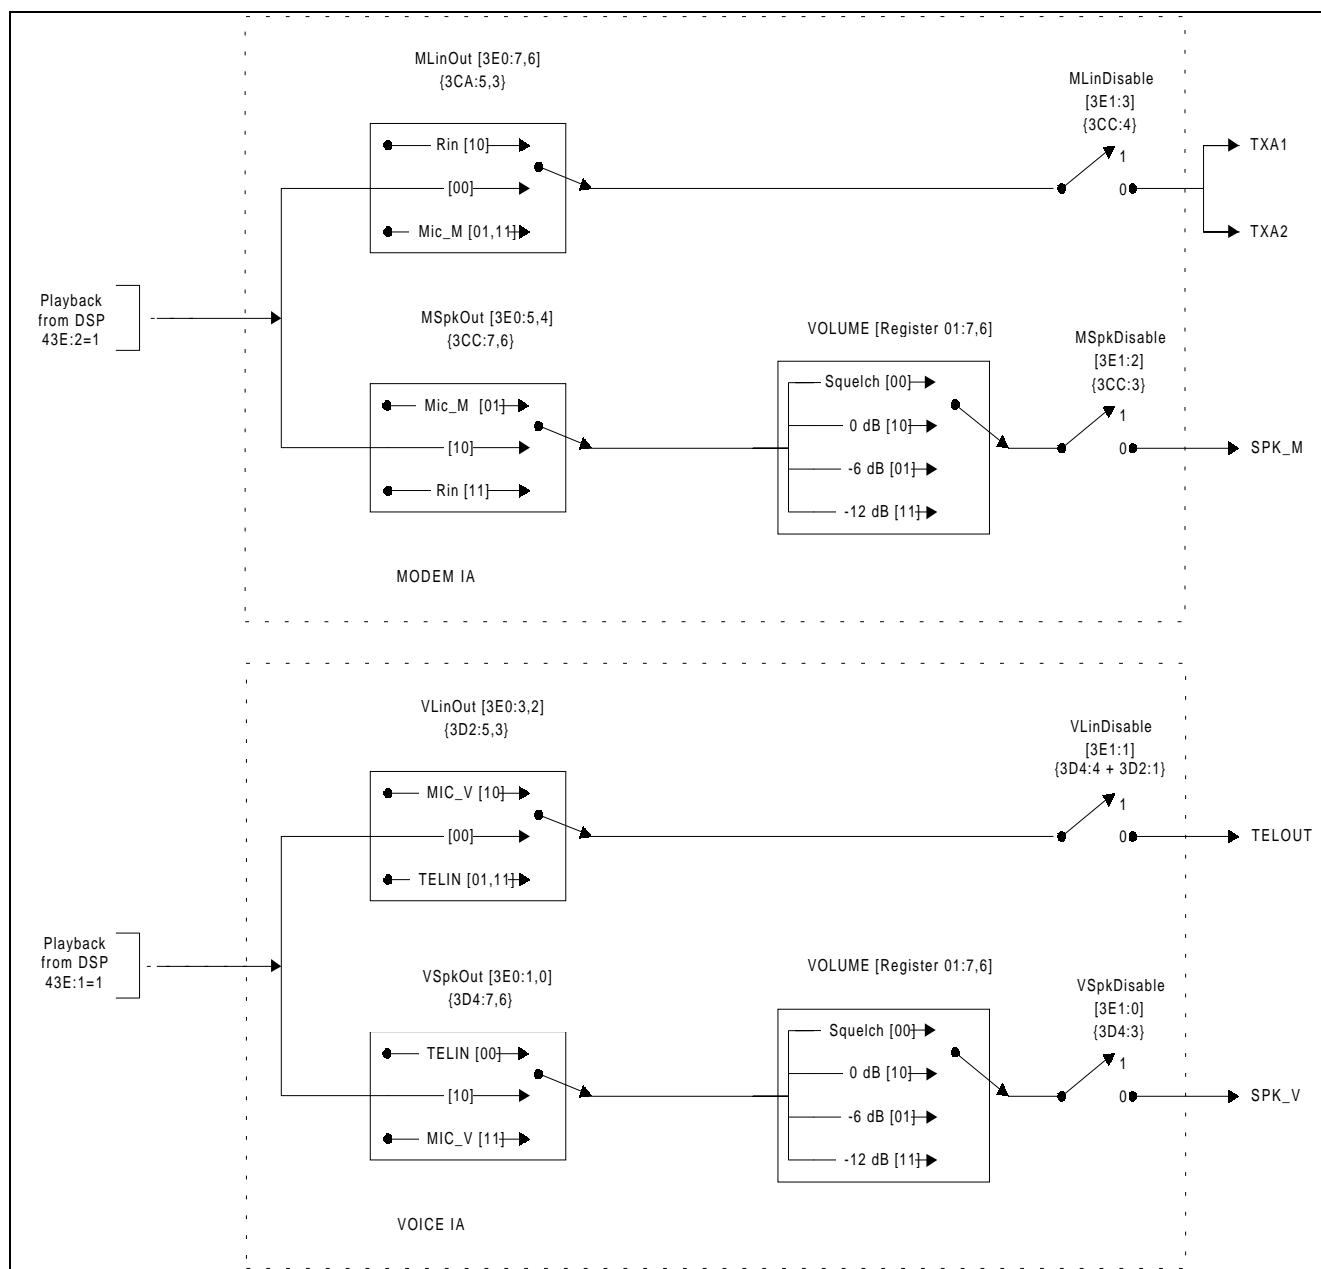

Figure 12-2. Transmit Voice Paths

Note 1:

Addresses shown in { } access the voice path directly in the L8570 and subs.

The older addresses in [] are not supported in the L8771 and subs and are shown for reference only.

After configuring the desired in { } addresses, NEWC must **not** be set, otherwise some of the selected paths may be reset.

Note 2:

The SPK_M and SPKV outputs are both tied to the SPK pin on the device. Only one of these outputs should be enabled at a given time.

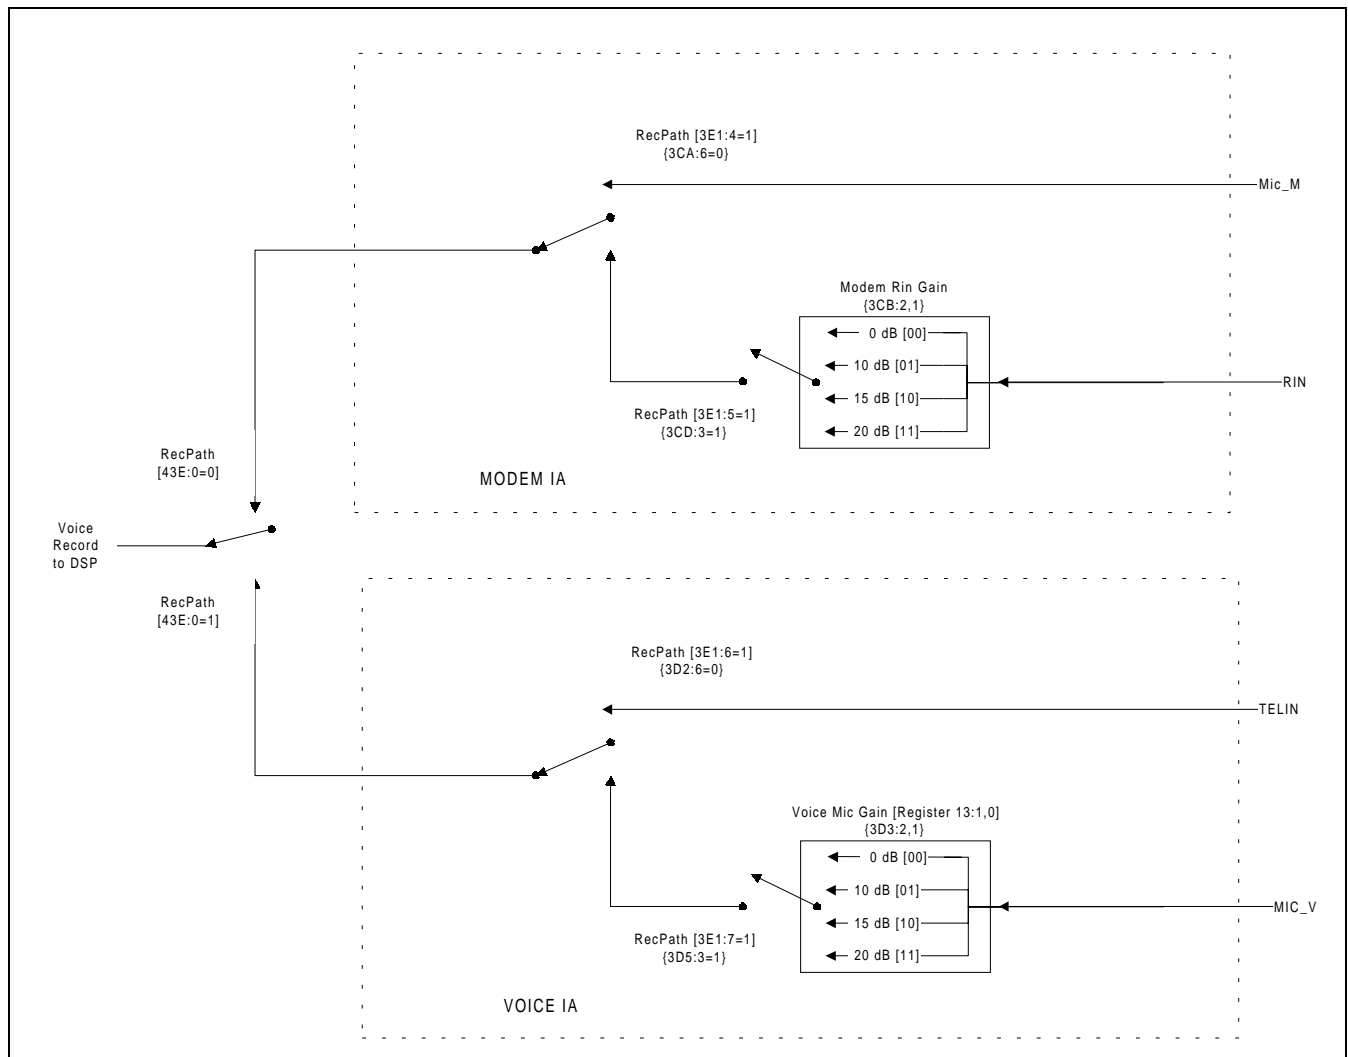

Figure 12-3. Receiver Voice Paths

Note 1:

Addresses shown in { } access the voice path directly in the L8570 and subs.

The older addresses in [] are not supported in the L8771 and subs, and are shown for reference only.

After configuring the desired in { } addresses, NEWC must **not** be set, otherwise some of the selected paths may be reset.

12.1.2 Volume and Microphone Level Control

Volume Control (01h:7-6)

The VOLUME bits (01h:7-6) control the Voice and Modem speaker volume.

00	Squelch
01	6 dB attenuation
10	0 dB attenuation
11	12 dB attenuation

Voice Microphone Level Control (13h:1-0)

The VMicLVL bits (13h:1-0) control the Voice mic level.

00	00 dB gain
01	10 dB gain
10	15 dB gain
11	20 dB gain

12.1.3 Voice Loopback (Sidetone Feature)

A “voice loopback” feature takes samples from the selected receiver path and plays them back out the selected transmitter path(s). This is a “digital” loopback as opposed to the “analog” or “IA-loopback” features described above in the Line Output and Speaker Output sections. Sidetone can be used for a “music-on-hold” mode. For example, the receive voice samples can be taken from the MDP microphone input (MICM) and then played out over the MDP line out (TXA1/TXA2). The sidetone feature can be used in conjunction with recording. Addresses B6Bh and B69h control the amount of loopback leakage for the modem and voice IA, respectively. **Note:** TXV must be set to enable this feature.

12.1.4 Voice Record, Playback, and Tone Detector Control Register (Address 43Eh)

Bit 3 Tone Detection Path Select

- 0 = Detect tone from Modem IA
- 1 = Detect tone from Voice IA.

Bit 2 Enable Voice Playback to the Modem IA (TXV must be 1)

- 1 = Enable voice playback to the Modem IA.
- 0 = Disable voice playback to the Modem IA.

Bit 1 Enable Voice Playback to the Voice IA (TXV must be 1)

- 1 = Enable voice playback to the Voice IA.
- 0 = Disable voice playback to the Voice IA.

Bit 0 Voice Record Path Select

- 1 = Record from Voice IA.
- 0 = Record from Modem IA.

12.1.5 Voice Mode Sample Rate Select Control Bit (Address 690h)

Bit 7 Select Modem IA Sample Rate Same as Voice IA

- 0 = Modem IA not set to same sample rate as voice IA setting.
- 1 = Modem IA set to same sample rate as voice IA setting.

Note: The default sample rate in CONF ACh is 8 kHz for both modem and voice IA. If changing the voice IA sample rate, bit 7 must be set when in CONF mode ACh to force the modem IA to the same sample rate. In CONF modes other than ACh, bit 7 need not be set. This allows the serial voice operation to run concurrently at any sample rate while the modem IA performs data mode operations.

Bits 2-0 Select Voice IA Sample Rate

- 001 = Voice IA set for 7.2 kHz sample rate
- 010 = Voice IA set for 8 kHz sample rate
- 100 = Voice IA set for 11.025 kHz sample rate

12.1.6 DTMF Generation/Detection Sample Rate Control Bit (Address 691h)

- Bit 6** If the default 8 kHz sample rate is changed to 7.2 kHz, set this bit to allow the DTMF generation and DTMF detection to follow the new sample rate change. The same is true if the sample rate is changed from 7.2 kHz back to 8 kHz.

12.1.7 Voice Mode Interface Control Bits (Address 692h)

Bit 7 Enable/Disable 8 kHz to 7.2 kHz Sample Rate Conversion for Tone Detectors

- 0 = Disable 8 kHz to 7.2 kHz sample rate conversion for tone detectors.
 1 = Enable 8 kHz to 7.2 kHz sample rate conversion for tone detectors. Allows tone detection to run at 7.2 kHz when voice sample rate is set for 8 kHz in CONF mode ACh.

Bit 6 Enable/Disable Full-Duplex Speakerphone

- 0 = Disable full-duplex speakerphone.
 1 = Enable full-duplex speakerphone.

Bit 5 Select 16-bit Linear/8-bit PCM Voice Samples

- 0 = 16-bit linear voice samples.
 1 = 8-bit PCM voice samples.

Bit 0 Select Serial/Parallel Interface Voice Samples

- 0 = Parallel interface host samples.
 1 = Serial voice samples 0n SR8OUT and SR8IN.

12.1.8 A-Law/ μ -Law Select Control Bit (Address 39Bh)

Bit 7 Select A-Law/ μ -Law

- 0 = μ -Law PCM samples.
 1 = A-Law PCM samples

12.1.9 Voice Mode Setup Example

To setup Voice Mode:

1. Set CONF = ACh.
2. Set NEWC = 1.
3. Set 43Eh according to desired playback, record and tone detection path.
4. Set TXV=1 for playback mode or RXV=1 for record mode.
5. Set the desired voice paths.
6. Set 690h = 82h for 8 kHz sample rate, or = 81h for 7.2 kHz sample rate.
7. Set 691h:6 = 1 if the DTMF generation and DTMF detection is to follow the new sample rate.
8. Set 692h = 80h for linear parallel interface samples and enable 8 kHz to 7.2 kHz conversion filter for tone detection. If the sample rate conversion filter for tone detection is not desired, clear bit 7/692h.
9. Set VINIT and wait for it to clear.

12.1.10 Voice Idle Mode

It is recommended that RXV be set when operating in voice idle mode from configuration ACh. This allows the transmitter to be used for tone generation (like dialing).

12.1.11 Voice AGC

See Section 11.3.

12.2 SPEAKERPHONE CONFIGURATION

12.2.1 Speakerphone Interface Memory Registers

The speakerphone registers are:

Register	7	6	5	4	3	2	1	0
14	SpDTMF	TonSpkE	TonLinE	—	—	SpRIEn	—	
13	—	VOLUP	VOLDWN	—	MuteSp	MuteMic	VMicLVL	

Note: The speakerphone registers are shared with other data-mode definitions.

12.2.2 DTMF and Dual Tone Modes

DTMF dialing can be sent to the line (DTMF = 1) and/or to the speaker (SpDTMF = 1) (see Table 12-1).

The dial digit is sent by writing to TBUFFER (similar to how it is done in mode 81h). To send a DTMF digit, write its number into TBUFFER. For example, to send the DTMF digit "4" to both the line and the speaker, set both SpDTMF and DTMF = 1 and then write a 04 into TBUFFER.

Table 12-1. DTMF Routing

DTMF	TonLinE	Dual Tone Mode	SpDTMF	TonSpkE	Dual Tone Mode
1	x	DTMF dialing to the line	1	x	DTMF dialing to the speaker
0	1	Dual Tone (using RTS)	0	1	Dual Tone (using DTR)
0	0	No tones	0	0	No tones

The dual tone parameters addresses are listed in Table 12-2.

Table 12-2. Dual Tone Frequency Parameters

Dual Tone Function	Address (Hex)
Line Dual Tone 1 Amplitude	868
Line Dual Tone 1 Frequency	968
Line Dual Tone 2 Amplitude	869
Line Dual Tone 2 Frequency	969
Number of Line Tones -1	B68
Speaker Dual Tone 1 Amplitude	86A
Speaker Dual Tone 1 Frequency	96A
Speaker Dual Tone 2 Amplitude	86B
Speaker Dual Tone 2 Frequency	96B
Number of Speaker Tones -1	B6A
Note: Setting NEWC will reset these locations. All addresses are 16-bit access.	

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

In dual tone mode, RTS is used to control the line dual tone transmitter and DTR is used to control the speaker tone transmitter.

The equations for the frequency and power values are:

Frequency: $N = F/0.109863$ for 7200 Hz

Multiple N by 7200/8000 for 8000 Hz

Power: $N = 6224 (10^{Po/20})$

Where:

N is the decimal equivalent of the hex number written to RAM.

F is the frequency in Hz and Po is the power in dBm (based on a 600 ohm load).

The control parameter functions are:

- SpRIEn enables Ring detection. A tone pair is sent to the speaker when SpRIEn is enabled and incoming ring is detected.
- VOLUP and VOLDWN control the speaker volume in ± 2 dB increments in addition to the VOLUME bit field selection.
- MuteMic and MuteSp control the muting of the microphone and the speaker, respectively. To be more precise, the MuteSp bit mutes the "line input".
- MMicLVL and VMicLVL control the modem and voice microphone input levels, respectively.

12.2.3 Speakerphone Mode Setup Example

To setup Speakerphone Mode:

1. Set CONF = ACh.
2. Set NEWC = 1.
3. Set 6/692h = 1.
4. Set VINIT and wait for it to clear.

12.2.4 "Room Monitor" Mode

To operate in "room monitor" mode:

1. Set CONF = ACh.
2. Set NEWC = 1.
3. Set RXV = 1.
4. Select the output to TXA1/TXA2 to come from the modem playback path (43Eh:2 = 1).
5. Setup the voice IA mic level to 20 dB gain (14).
6. Disable the output to SPKV, SPKM, and TELOUT.
7. Set VAGC.
8. Select the "record" path to come from the Voice IA (43Eh:0 = 1).
9. Set VINIT and wait for it to clear.

In this mode, the tone detectors (including the DTMF receiver) are operational.

12.2.5 Speakerphone Conversation Record

When in speakerphone mode, the conversation may be recorded by enabling variable gains on both the transmit and receive paths and reading samples from RBUFFER just as in voice pass through mode with the exception that RXV must be set to 0. The gain locations are AF0h for the transmitter (local speaker) and AF1h for the receiver (incoming voice). Both of these locations default to 0000h. The higher the value, the higher the gain.

Record procedure:

1. Connect in speakerphone mode.
2. Ensure RXV = 0.
3. Write the desired gain values in AF0h and AF1h; a value of 2000h is generally suitable.
4. Read in 16-bit samples through RBUFFER as per voice pass through record procedure. (See Section 11.)

12.3 Voice Mode, Tone Detection and Tone Generation Paths

Figure 12-4 illustrates the complete voice mode, tone detection and tone generation paths when in CONF mode ACh. The scaling address shown (A0Fh, B0Fh, A0Ah and B0Ah) are reset to default with NEWC. These gains may be adjusted if needed. The values are 16 bit and may be positive or negative. A change of 300h-400h up or down from the default value corresponds to approximately 2 dB of gain or attenuation, respectively. This same block diagram applies when in speakerphone mode, however, echo cancellers and other speakerphone related functions are not shown.

Figure 12-4. Voice Mode, Tone Detection and Tone Generation Paths

This page is intentionally blank.

13. SIMULTANEOUS AUDIO/VOICE AND DATA (AUDIOSPAN)

All RAM addresses mentioned in this section are 16-bit access if 12th bit of address field is set, or 8-bit access if 12th bit is reset, unless otherwise specified.

13.1 ML144/V.61 (V.32bis) AUDIOSPAN CONTROL

13.1.1 AudioSpan Control Registers

AudioSpan Control Register 1 (Address 439h)

Bits 7-2 **Reserved**

Bit 1 **Host AudioSpan Enable/Disable (Host-SVDEn)**

1 = Enable host AudioSpan.

0 = Disable host AudioSpan.

Bit 0 **V.8bis Detector Enable/Disable (V8bDetEn)**

1 = Enable V.8bis detector.

0 = Disable V.8bis detector.

AudioSpan Control Register 2 (Address 400h)

Bit 7 **Half-Duplex Gain Control Enable/Disable (HDXgcEn)**

1 = Enable half-duplex gain control. (Recommended for mic/spkr operation or when handset echo canceller is used.)

0 = Disable half-duplex gain control.

Bit 6 **Mic AGC Enable/Disable (QmicAGCen)**

1 = Enable AGC on mic. (Not recommended for headset or handset operation.)

0 = Disable AGC on mic.

Bit 5 **Handset or Spkr/Mic Select**

1 = Select Handset (TELIN/TELOUT lines selected).

0 = Select Spkr/mic (SPKRM/MICM lines selected).

Bits 4-3 **Reserved**

Bit 2 **Voice Squelch (VoiceSq)**

1 = Squelch voice. Set this bit to signal off-hook status to remote modem.

0 = Enable voice.

Bit 1 **AudioSpan Symbol Rate Select**

1 = 3000.

0 = 2800.

Bit 0 **Reserved**

Maximum Voice+Data Rate (Address 42Ah)

Bits 7-5 **Reserved**

Bit 4 **Remote Tx Silence Detection Enable/Disable**

1 = Enable remote Tx silence detection.

0 = Disable remote Tx silence detection.

Bit 3 **Reserved**

Bits 2-0 **Maximum Voice+Data Rate**

000 = 4800 bps (default) (does not allow silence detection to be disabled).

001 = 4800 bps (allows silence detection to be disabled).

010 = 4800 bps (allows silence detection to be disabled).

011 = 7200 bps

100 = 9600 bps

101 = 12000 bps

110 = 14400 bps

111 = 14400 bps.

Bit 0 **Reserved**

13.1.2 ML144 Mode Selection

To enable ML144/V.61, perform the following:

1. Enable Host AudioSpan (set bit 439h:1 = 1).
2. Select a V.32bis configuration (e.g., set CONF = 76h), or select V.8 (set CONF = AAh) with 306h:6 = 0 to disable V.34.
3. Set NEWC to 1.

13.1.3 Detecting Remote Off-Hook Status

Setting bit 400h:2 squelches the AudioSpan audio transmission and causes bit 419h:7 to be set on the remote modem. Bit 400h:2 should be set when the audio link is in an on-hook state.

When the handset is picked up or the mic is enabled, the host should reset bit 400h:2. This will cause bit 419h:7 to reset on the remote modem, indicating an audio link request.

13.1.4 Generating Ring and Ringback

A dual-tone generator is available during a ML144 AudioSpan connection. When enabled, the AudioSpan audio is suppressed and the tone(s) is routed to the speaker or handset, depending which is enabled. This can be used to generate a ring signal when detecting a remote off-hook status as described above. It may also be used to generate a local ringback signal while waiting for the remote user to answer.

Tone Generator Enable/Disable (Address AB0h)

Bits 7-0 **Tone Generator Enable/Disable**

Non-0 = Enable tone generator.

0 = Disable tone generator.

The tone generator is enabled by making address AB0 non-zero. This value is reset with NEWC, RTRN or RREN.

Tone 1 Frequency (Address BB0h) and Tone 2 Frequency (Address BB2h)

The frequency equation is:

$$N = F/0.13745$$

Where: N is the decimal equivalent of the hex number written to RAM and F is the frequency.

Tone 1 Amplitude (Address AB0) and Tone 2 Amplitude (Address AB2h)

The power equation is:

$$N = 2033(10^{P_o/20})$$

Where: N is the decimal equivalent of the hex number written to RAM and P_o is the power level in dBm.

The equation is based on VOLUME bits (01h:7-6) = 2.

Generating Ringback Example

1. Set ringback frequencies of 440/480 Hz: Write 0C81h and 0DA4h to addresses BB0h and BB2h, respectively.
2. Set a suggested power level of -20 dBm for each frequency: Write 00CBh to addresses AB2h and AB0h.
3. Enable the tone generator (start the tone transmission): Write a non-zero value to address AB0h. **Note:** AB0 should be that last address written to.
4. Control the cadence of the ringback: Write a zero and non-zero value to address AB0h as required.

13.1.5 ML144/V.61 AudioSpan Rate Sequence

The values in address 42Ah are used to generate the Tx Rate sequence words 2 and 3. The ARC bit must be set = 1 to allow the modems to negotiate the highest common voice+data rate to be used.

AudioSpan Rate Sequence Word 2 and Word 3 are stored in RAM and are set up from contents of address 42Ah after NEWC is set. They can be changed directly by the host, without using masking registers, after DTR is set. Tx Rate Sequence Word 1 and mask register are the same as V.32bis.

Tx Rate Sequence Word 2: Low Byte (Address 42Eh, Default = 11h); High Byte (Address 42Fh, Default = 0Dh)

Rx Rate Sequence Word 2: Low Byte (Address 432h); High Byte (Address 433h)

High Byte (Address 42Fh/433h) Definition

Bit 7	0
Bit 6	0
Bit 5	0
Bit 4	0
Bit 3	1
Bit 2	1 = Voice+data rate at 4800 bps is enabled (default)
Bit 1	1 = Voice+data rate at 9600 bps is enabled
Bit 0	1

Low Byte (Address 42Eh/433h) Definition

Bit 7	0
Bit 6	1 = Voice+data rate at 7200 bps is enabled
Bit 5	1 = Voice+data rate at 12000 bps is enabled
Bit 4	1
Bit 3	1 = Voice+data rate at 14400 bps is enabled
Bit 2	0
Bit 1	0
Bit 0	1

Tx Rate Sequence Word 3: Low Byte Address (430h, Default = 93h); High Byte Address (431h, Default = 01h)

Rx Rate Sequence Word 3: Low Byte Address (434h); High Byte Address (435h)

High Byte (Address 431h/435h) Definition

Bit 7	0
Bit 6	0
Bit 5	0
Bit 4	0
Bit 3	0
Bit 2	0
Bit 1	0
Bit 0	1

Low Byte (Address 430h/434h) Definition

Bit 7	1
Bit 6	0
Bit 5	0
Bit 4	1
Bit 3	0
Bit 2	0
Bit 1	1 = Silence detection enabled at receiving transmitter (default)
Bit 0	1

13.1.6 Selecting Voice+Data Rates

The value in address 42Ah can be used for the initial handshake, retrains and rate renegotiations. If a 0 is placed in address 42Ah, the user may modify the rate sequence directly through addresses 42Fh/42Eh. Rate changes may easily be accomplished by setting the desired speed in address 42Ah followed by setting RREN, however, using the rate sequence masks at address 42Fh/42Eh gives the user more flexibility. Changing CONF and setting RREN will change the data-only rate for when silence detection is being used. The voice+data rate will not be affected.

13.1.7 Maximum Voice+Data Rate

The voice+data rate is defined as the user data rate when audio information is being sent. Assuming minimal line disturbances, the maximum voice+data rate is 14.4k bps in ML144, however, a degradation in audio quality can be observed at this high rate. It is suggested that the voice+data rate be maintained at two speeds below the maximum possible data-only rate for the given line conditions (one speed is a difference of 2400 bps). For example, a line capable of supporting a 14.4k data-only connection would be able to support a 9.6k voice+data connection with good audio quality.

13.1.8 Data-only or Voice+Data Detection

If silence detection is used to allow the MDP to automatically shift between voice+data and data-only mode, bit A35h:E may be used to determine the state of the MDP. If set, bit A35h:E indicates the MDP is in data-only receive mode. When reset, the MDP is in voice+data receive mode.

13.1.9 Speaker Attenuation/Gain Control

Speaker Gain Control

The speaker gain may be controlled through the VOLUME bits (01h:7-6):

Speaker Attenuation (dB)	Value in 01h:7-6 (Bin)
Speaker off	00
0 dB (high volume)	01
6 dB (medium volume)	10
12 dB (low volume)	11

The speaker gain may also be altered through address 990h. This location is reset to default after a RREN and is adjustable only when the modems are connected. The speaker volume is relative to the microphone gain of the remote audio source. Values written to address 990h do not correspond to absolute output levels but rather to relative changes in output level. The following table illustrates the relative gain in 2 dB steps:

Speaker Relative Gain (dB)	Value in 990 (Hex)
+10	FC00 (maximum)
+8	FA00
+6	F800
+4	F400
+2	F200
0	F000 (default)
-2	EC00
-4	EA00
-6	E700
-8	E400
-10	E200

13.1.10 Microphone Gain Control

The microphone gain is controlled through bits 3D3h:2-1:

Microphone Gain (dB)	Value in 3D3h:2-1 (Bin)
0	00
10	01
15	10
20	11

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

The gain may also be altered through address B7Eh. This location is reset to default after a RREN and is adjustable only when the modems are connected. The total input gain should not bring the input signal level above -16 dBm to avoid input saturation. The following table illustrates the relative gain in 2 dB steps:

Microphone Relative Gain (dB)	Value in B7E (Hex)
+10	1500
+8	1200
+6	0F00
+4	0C00
+2	0A00
0	0800 (default value)
-2	0500
-4	0200
-6	FF00
-8	FD00
-10	FA00

The equation to calculate the relative gain change for both mic and speaker is as follows:

$$\text{Gain change in dB} = 20\text{Log}(M\#2) - 20\text{Log}(M\#1)$$

Where:

$$M = 2^{(x + y/2048)}$$

The 16-bit signed value is broken down as: xxxxyyyyyyyyyyyy (y = bits 0-A and x = bits B-F)

M#1 is calculated based on the current gain value.

M#2 is calculated based on the new gain value.

13.1.11 TELIN/TELOUT Gain Control

When using TELIN/TELOUT for handset operation, the gain control has to be through address B7Eh for TELIN and address 990h for TELOUT. The VOLUME bits and mic gain control at address 3D3h do not apply.

13.1.12 Handset Echo Canceller

When bit 400h:5 is set for handset operation, the handset echo canceller must be enabled to avoid echoes on the remote end. To enable the echo canceller, write 8004h to address A5Ch. If read back, a value of 0004 or 4004h will be present. 8004h should be written to A5C once the modems are connected and handset operation is desired.

The half-duplex gain control bit (400h:7) should also be set to further suppress the echo. When bit 400h:5 is reset for headset or mic/spkr operation, disable the echo canceller by writing 0000 to A5Ch.

13.2 HOST INTERFACE SELECTION AND SETUP

There are basically three audio interface possibilities:

1. Microphone/Speaker (Mic/SPKR): Where an external microphone and speaker is used. Ties into the MICV and SPKR-V pins.
2. Headset: Where a headset with built-in microphone or an external audio source and speaker is used. The external audio source can be in the form of a microphone, CD or DAT player. Ties into the MICV and SPKR-V pins.
3. Handset: Where a telephone handset is used. Ties into the TELIN and TELOUT pins.

The first two interfaces both use the same pins on the device but are in separate categories since some options such as volume and gain control may require different settings between the two modes.

Configuration for Interface Setups

To Select Mic/SPKR:

1. Turn off handset mode: Reset bit 400h:5 to 0.
2. Turn on the mic AGC if desired: Set bit 400h:6 to 1.
3. Enable the half-duplex gain control: Set bit 400h:7 to 1. *
4. If on, turn off the handset echo canceller: Write 0 to A5Ch. (Only matters if in connect mode.)
5. Adjust volume to the desired level: e.g., set VOLUME bits to 2.

To Select Headset:

1. Turn off handset mode. Reset bit 400h:5 to 0.
2. Turn off the mic AGC. Reset bit 400h:6 to 0.
3. Although not necessary, disable the half-duplex gain control: Reset bit 400h:7 to 0.
4. If on, turn off the handset echo canceller: Write 0 to A5Ch. (Only matters if in connect mode.)
5. Adjust volume to the desired level: e.g., set VOLUME bits to 2.

To Select Handset:

1. Turn on handset mode: Set bit 400h:5 to 1.
2. Turn off the AGC. Reset bit 400h:6 to 0.
3. Enable the half-duplex gain control: Set bit 400h:7 to 1. *
4. Turn on the handset echo canceller after connected: Writing 8004h to A5Ch.
5. Adjust volume as desired: Use speaker scale location 990h (default F000h). Note that this location may get reset after RRENs or RTRNs. **Note:** VOLUME bits do not apply in handset mode.

* Note that the half duplex gain control does not render the audio communication half duplex. It simply dynamically adjusts input and output gains to minimize acoustic echoes.

13.2.1 Typical Operation and Selection of User Interface

After a connection is accomplished, the audio channel should typically be off until an audio link is desired, therefore, the Voice squelch bit 400h:2 should be set. This is also referred to as the "User Command Data Mode bit". It signifies that the user wishes to remain in data mode with no audio.

When bit 400h:2 is set, the remote modem sets bit 419h:7, indicating that the other modem is "on-hook" (no audio link desired). It is suggested that the interface defaults to the Mic/SPKR configuration so that a simulated ring signal may be heard through the speaker. The ring signal can also be heard if headsets are used (assuming they are being worn). The application may want to flash some sort of indicator when an audio link request is detected if headsets are used. There is no currently no method of ringing the phone itself. A possible solution would be for the voice relay to be asserted only when a remote audio link request is detected and the voice relay line could then be used to cause external ring voltage circuitry to ring the phone.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Assuming one scenario at a time:

Scenario 1: User Picks Up the Handset

1. When the handset is picked up (LCS is detected), the user wants an audio link, therefore, the handset configuration should be initiated and bit 400h:2 (voice squelch) should be reset. This causes bit 419h:7 on the remote modem to turn off.
2. The remote modem may then signal a ring by using the dual tone generator and the local modem, where the handset was picked up, may generate a ringback tone (see the description on how to generate ring and ringback). The ringback tone should only be generated if bit 419h:7 is set, indicating that the remote modem is still "on-hook".
3. When the remote modem answers the audio link request by either picking up the handset or invoking Mic/SPKR or headset operation, it should turn off its simulated ring and turn off bit 400h:2 which will cause the local modem to reset bit 419h:7. Upon detecting 419h:7 going off, the local modem should stop generating ringback. The audio link is now enabled.

Scenario 2: Using Headset or Mic/SPKR

1. When headsets or Mic/SPKR is used to initiate the audio link request, there is no line current sensing to know when an "off-hook" status is requested. The application must have a means of enabling this mode and instructing the MDP to reset bit 400h:2 for an audio link request. It is advisable that the application distinguish between headset and Mic/SPKR operation since the AGC is recommended for Mic/SPKR use but not for headset operation.

Scenario 3: Hanging Up (Terminating the Audio Link)

1. When either the local or remote modem goes back "on-hook", bit 400h:2 should be set again to squelch the audio link. This will cause the other modem (the one that has not hung up yet) to have bit 419h:7 set. By the same token, the modem that terminated the audio link will still see its bit 419h:7 reset until the other party "hangs up". This does not mean the modems should again generate ring or ringback tones!
2. When the remote modem hangs up, the local modem should not generate ringback based on 419h:7 until it has gone "on-hook" and back "off-hook".
3. The local modem that "hung-up" should not generate ring until it has seen bit 419h:7 go from 0 to 1 and back to 0 again, indicating that the remote modem went "on-hook" and back "off-hook". In other words, ring and ringback tones should not be generated again until after both modems have been in a terminated audio link state.

Ring or No Ring?

Some applications may require the audio link always be enabled with no control from the modem, particularly in headset operation. In this case, bit 400h:2 should not be set and since 400h:2 is not set and therefore 419h:7 is not set on either modem, no ring or ringback tones should be generated.

If user audio link control and ring/ringback tones are to be used:

- The MDP will generate ring if bit 400h:2 is set and bit 419h:7 is reset. If 400h:2 is reset or if 419h:7 is set, ring tones will be off.
- The MDP will generate ringback if bit 400h:2 is reset and bit 419h:7 is set. If 400h:2 is set or if 419h:7 is reset, ringback tones will be off.

Note: Remember that ring and ringback tones should not be generated unless both modems have previously been in a terminated audio link state at a some time.

Muting the Outgoing Audio

Although the outgoing audio is squelched when bit 400h:2 is set, it should not be used for that purpose once the audio link is established. If used, it may terminate the audio link depending on how the received bit 419h:7 is interpreted. The input scale value at address B7Eh could be used but causes the remote eye to reduce down to single points.

A noise generator is available on the outgoing audio path. It is enabled by writing a non-zero value to address BB3h. A value of 0005h is suggested. The higher the value, the higher the noise. The value of 0005h is low enough to not be heard but will maintain a proper EQM value on the remote modem. If silence detection is enabled, the value of 0005h will cause the remote modem to shift to a data only mode rate which will automatically mute the received audio as well.

An example of when this should be used is while waiting for the remote modem to respond to an audio link request. When the local modem goes "off-hook", the outgoing audio path is enabled since bit 400h:2 is reset. This means that all input audio is getting across to the remote modem and can be heard over the speaker or headset. If the remote modem is generating a simulated ring, the audio which is coming from the local modem input can be heard between ring tone generation.

In order to prevent this, the local modem initiating the audio link request should mute its outgoing audio by writing 0005h (or desired value) to BB3. When the local modem detects the remote "off-hook" status (419h:7 = 0), the outgoing audio should be enabled again by writing 0000h to BB3.

14. K56FLEX SETUP AND CODE CHANGES

This section describes the configuration procedure for K56flex downloadable data pump and provides a general description of the K56flex handshake. All RAM accesses are 8 bit (Method 1) unless otherwise noted.

Note: This section refers to "client" and "server" modems. For example, the RP56LD/SP MDP is used in a client modem application and the RL56DDP is used in a central site modem (CSM) server modem application.

Note: Refer to Section 16 for more information on K56flex-only RAM code, download procedures, and interaction with V.90 mode.

14.1 K56flex SETUP

In a K56flex connection, the client modem (e.g., RP56LD/SP) will receive in K56flex PCM mode and will transmit a V.34 modulated signal. The server modem (e.g., RL56DDP) will do exactly the opposite. When a successful K56flex connection is established, the CONF register indicates the receiver configuration and speed (Table 14-1) and the SPEED bits indicate the transmitter configuration and speed (Table 14-2). The client modem's CONF value will change from AAh (V.8) to 9Xh if a K56flex handshake has been negotiated. The CONF value may change to a different 9Xh value when the connection is complete (RLSD = 1) depending on rate masks and ARA decisions. The server modem will contain a CXh value in CONF to indicate the V.34 receive speed.

In a K56flex connection, the state of the ORG bit simply determines which modem will send answer tone and which modem will detect it. After a V.8 procedure, similar to the standard V.8 used with V.34, the server modem will always be in an "answer" handshake mode, sending its half-duplex TRN first and the client modem will be in an "originate" handshake mode, sending its half-duplex TRN second. The same handshake sequence will occur regardless of who originated the call, i.e., the ORG bit does not influence the handshake sequence which takes place after V.8. The server modem will typically always answer calls while the client modem will usually originate them. In the event a server modem must use a call back feature, the ORG bit will have to be set on the server modem in order to detect answer tone. In this type of situation, the ORG bit will automatically change to 0 on the server modem and to 1 on the client modem after V.8.

14.1.1 Client Modem (Analog Modem) Configuration Procedure

Note: This section is valid only for K56flex-only RAM code. See Section 16 for interaction with V.90 mode.

1. Set CONF = AAh to select K56flex configuration.
2. Write the desired K56flex receive speed in address 409h by writing 9Xh, where X indicates the desired receive data rate. X is in increments of 2000 bps beginning with 32,000 when X = 1. If the ARA feature (EARC = 1) or the rate masks are used, the value in 409h may be left at default. See Table 14-1.
3. Set bit 406h:0 to enable the K56flex receiver.
4. Set ORG bit = 1 if originating, else reset ORG = 0.
5. Set bit 13Fh:6 to enable asymmetric data rates.
6. Set EARC and/or AUTO if desired.
7. Set NEWC.
8. Set DTR to initiate handshake.

14.1.2 Server Modem (Digital Modem) Configuration Procedure

Note: This section is valid only for K56flex-only RAM code. See Section 16 for interaction with V.90 mode.

1. Set CONF = AAh to select K56flex configuration.
2. Write the desired V.34 receive speed in RAM address 309h by writing CXh, where X indicates the desired receive data rate. X is in increments of 2400 bps. If the ARA feature (EARC = 1) or the rate masks are used, the value in 309h may be left at default. See Table 14-1.
3. Set bit 406h:0 to enable the K56flex transmitter.
4. Set ORG bit = 1 if originating, else reset ORG = 0.
5. Set bit 13Fh:6 to enable asymmetric data rates.
6. Set EARC and/or AUTO if desired.
7. Set NEWC.
8. Set DTR to initiate handshake.

Table 14-1. K56flex Data Rate Versus Configuration and Data Rate Mask Values

X	Data Rate for CONF = CX and Rate Mask 605h or 604h = 0Xh	Data Rate for CONF = 9X and Rate Mask 605h or 604h = 0Xh
1	2400	32000
2	4800	34000
3	7200	36000
4	9600	38000
5	12000	40000
6	14400	42000
7	16800	44000
8	19200	46000
9	21600	48000
A	24000	50000
B	26400	52000
C	28800	54000
D	31200	56000
E	33600	Reserved

Table 14-2. K56flex Data Rate Versus Speed Bit Values

SPEED (Hex)	Data Rate (bps)	SPEED (Hex)	Data Rate (bps)
0	0-300	10	33600
1	600	11	32000
2	1200	12	34000
3	2400	13	36000
4	4800	14	38000
5	9600	15	40000
6	12000	16	42000
7	14400	17	44000
8	7200	18	46000
9	16800	19	48000
A	19200	1A	50000
B	21600	1B	52000
C	24000	1C	54000
D	26400	1D	56000
E	28800	1E	Reserved
F	31200	1F	Reserved

14.1.3 K56flex Bit Definitions

39Bh:7 - A-law / μ -law Selection. When set, A-law is enabled; when reset, μ -law is enabled. If the modems are configured opposite of each other, they will automatically fallback to V.34. If communicating over an A-law system, the server modem must have this bit set for all modes of operation. The client modem must set this bit only for K56flex operation. Other client modes are not affected.

401h:0 - K56flex Handshake in Progress. When set, this status bit indicates the modems are proceeding with a K56flex handshake. (Valid after SECTXB>2Xh.)

406h:1 - K56flex Transmit Level (Server Modem Only). Used on server modem to control the K56flex transmit level (1 = -6 dBm0, 0 = -12 dBm0).

406h:0 - K56flex Enable. If set, K56flex is enabled; if reset, K56flex is disabled.

409h - Desired K56flex Receive Speed. See Table 14-1.

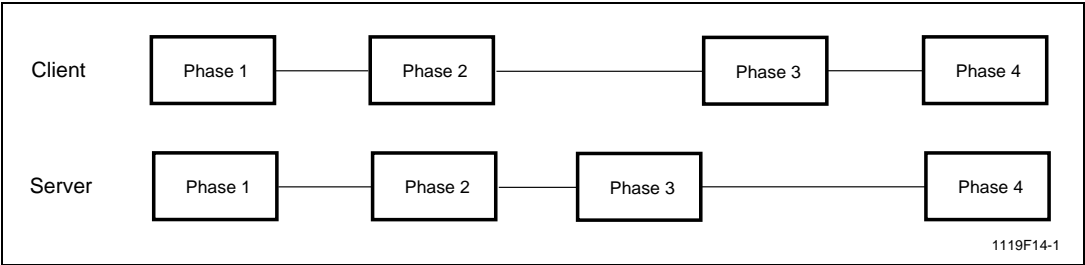

604h - Maximum Receive Rate Mask. See Table 14-1.

605h - Maximum Transmit Rate Mask. See Table 14-1.

The NEWC bit should be set after control bits have been setup as desired.

14.1.4 K56flex Handshake

The K56flex handshake is very similar to V.34. The modems first go through V.8bis then V.8, after which they exchange INFO0 parameters. Each modem then independently sends a probe signal followed by an exchange of INFO1 parameters. A half duplex TRN is then sent by each modem, starting with the server modem, followed by a full duplex TRN and an exchange of MP parameters. The handshake can be followed through the use of the SECTXB and SECRXB registers as in V.34 mode. After Phase 1 , the states are the same for both answer and originate mode. The handshake states are:

Handshake Sequence

Client and Server States During Phase 1 (after V.8bis)

Answer mode:

SECTXB = 0,1,2

SECRXB = 0,2,3

Originate mode:

SECTXB = 0,,2,3,4,5

SECRXB = 0,1,2

Client States During Phase 2 (answer & originate mode)

SECTXB = 20,21,22,28,29,24,25,2C

SECRXB = 20,22,23,27,28,29,2A,2D,2B,24,25,2C,2D,2E,2F

Client States During Phase 3 (answer & originate mode)

SECTXB = 40,44,45,46,47,48

SECRXB = 30,31,32,33,48

Client States During Phase 4 (answer & originate mode)

SECTXB = 62,63,64,65,66,67

SECRXB = 61,62,63,65,68

Server States During Phase 2 (answer & originate mode)

SECTXB = 20,21,22,23,24,25,26,27,28,2A,2C

SECRXB = 20,21,22,23,24,25,26,27,28,29,2A,2C,2E

Server States During Phase 3 (answer & originate mode)

SECTXB = 40,41,42,43

SECRXB = 40,41,46,47,48

Server States During Phase 4 (answer & originate mode)

SECTXB = 60,61,62,63,64,65,66

SECRXB = 60,63,64,65,67

Retrains

Retrains follow the same flow of transmitter and receiver states excluding phase 1. Rate renegotiations are a repeat of phase 4 and provide the following states:

Client States During Rate Renegotiation

SECTXB = 80,81,82,83,84,85,86,87

SECRXB = 83,84,85,68

Server States During Rate Renegotiation

SECTXB = 80,81,82,83,84,85,86

SECRXB = 83,84,85,67

14.1.5 Detecting K56flex

When a client modem calls into a server modem it will search for V8bis CRe. If V.8bis is detected, the modems proceed under the K56flex V.8bis startup. The modems will then proceed to establish a K56flex connection. Bit 401h:0 will set, indicating the handshake is proceeding in K56flex mode. This bit will set at the end of V.8 when the CONF value changes to 9Xh (client modem) or CXh (server modem). If the client modem cannot reply as a K56flex modem, the modems will proceed in V.8 and attempt a V.34 connection or will fallback to a lower modulation mode as needed if the AUTO bit is set.

If a client modem calls another client modem setup to answer as a K56flex modem, the connection will automatically fallback to V.34. The same is true if the modems are not both setup for A-law or μ -law or if the line probe has determined that K56flex cannot be supported over the selected line. Bit 401h:0 will be cleared at the end of phase 2 if the modems fallback to V.34. The host should check this bit after SECTXB>30h to confirm if the handshake is proceeding in K56flex or V.34 mode.

14.1.6 EQM Readings

The EQM readings and interpretation for the server receiver remain unchanged when compared to the RC336ACF or RC288DPX device in V.34 mode. The same is true for the client modem if connected in V.34 mode, however, the client modem, when receiving a K56flex PCM signal, will provide much smaller values for EQM. Values less than 0300h are typically good and above 0400h are bad. The EQM trip point for fallback or fall forward decisions may not be the same across all speeds. Each speed may require its own EQM limit. The same RAM address is used (20Ch) for reading EQM during the handshake and may be used while in data mode as well.

For the client modem only, a alternative location at 810h (16 bits), which provides larger and more stable values, may be read during data mode instead of the EQM at 20Ch while in K56flex mode. The EQM values at 810h are only valid in data mode and may not be used during the handshake. Although EQM values in 810h are updated during a V.34 or V.32bis connection and should reflect similar values as those seen in 20Ch, the preferred EQM address for these modes is still 20Ch. As a rule of thumb, fall forward and fallback decisions should be based on maintaining the EQM average reading at location 810h at value near 2000h-2500h. EQM readings may differ slightly between μ -law and A-law.

14.1.7 Automatic Data Rate Selection

Automatic Data Rate Selection (ARA), when EARC = 1, also applies in K56flex mode, however, the ARA-in-RAM featured used in V.34 (server receiver in K56flex mode or V.34 mode) does not apply on the client modem when receiving a K56flex PCM signal. The K56flex mode uses predetermined EQM thresholds in order to select the proper data rate during the initial handshake or retrain when EARC = 1. The aggressiveness of the data rate selection may be influenced by changing the EQM scaling at A29h (16-bit access). The value at A29h may be changed in phase 3 (SECRXB = 4Xh). The default value is 0100h. A change of 0010h-0020h is enough to shift the data rate selection up or down by one speed. Increasing A29h will increase the EQM value, causing the ARA algorithm to select a less aggressive speed. Decreasing A29h will decrease the EQM value, causing the ARA algorithm to select a more aggressive speed. Upon connecting (RLSD = 1), the default value of 0100h may be written back to A29h. If not, the EQM value will remain higher or lower as scaled by the value in A29h.

Recommended Rate Selection Procedure

For more flexibility, the user may prefer to take control over the data rate selection by monitoring EQM during phase 4 and manually selecting the data rate based on predetermined EQM thresholds. Such a method is used in V.34 mode with the RCV288DPx and RC336ACF/DPFL V.34 data pumps. The procedure for manual speed selection for both handshakes and retrains is as follows:

K56flex Mode (Client Receiver):

1. Turn off the EARC bit once the handshake is known to be progressing in K56flex mode.
2. Wait for SECTXB = 63h.
3. Wait for LSB of 04Dh = 02h; waiting for transmitted TRN counter to get near end.
4. Quickly read 50 samples (to get a good average) of EQM at 20Ch (16-bit reads) and obtain a total sum (allocate 3 bytes for sum).
5. Based on average EQM value read, select a receive data rate by writing the value 0Xh in 2E4h where X = the corresponding data rate as shown in Table 14-1. The following EQM table is used in the Rockwell ACi firmware. The low byte of the 3-byte EQM sum is thrown out.

K56EQMTable		
If EQM > than ##,## (below) [HighByte,MidByte (Hex)]	Choose this Receive Data Rate	By writing this hex value to 2E4h
01,30	32 kbps	01
01,00	34 kbps	02
00,F0	36 kbps	03
00,E5	38 kbps	04
00,E0	40 kbps	05
00,D0	42 kbps	06
00,C0	44 kbps	07
00,B0	46 kbps	08
00,A6	48 kbps	09
00,95	50 kbps	0A
00,90	52 kbps	0B
00,50	54 kbps	0C
00,05	56 kbps	0D

V.34 Mode (Normal V.34 or Server K56flex Receive Mode):

1. Make sure EARC = 1 and ARA-in-RAM feature is enabled (3A5h:4 = 1).
2. Wait for SECRXB or SECTXB = 40h.
3. Read and save the symbol rate from 2E3h (will always be 3200 in K56flex mode). Based on the read symbol rate, write the suggested ARA-in-RAM values (see Table 14-3) to the specified locations (all are 8-bit writes)
4. Wait for SECTXB = 63h (handshake and RTRN).
5. Read and save value from 39Ah; this is the data rate the ARA has selected.
6. If the value is 04h or less (9.6k or less), or the rate mask has been set to speeds of 9.6k or less, or the symbol rate is less than 3000, end the procedure; otherwise continue.
7. Write 7800h to A29h (16-bit access), write 7F00h to B29h (16-bit access), and turn off the EARC bit; this scales the EQM value up and turns off ARA. (These locations will automatically be restored at connect time).
8. Wait for the LSB of 04Dh = 02h; waiting for transmitted TRN counter to get near end.
9. Quickly read 50 samples (to get a good average) of EQM at 20Ch (16 bit reads) and obtain a total sum (allocate 3 bytes for sum). The following EQM tables are used in the Rockwell ACi firmware. The low byte of the 3-byte EQM sum is thrown out.

Note: The older method of basing the EQM tables on a "divide by total samples" average may still be used along with the previously defined EQM tables:

- 10a. If in answer or originate mode at 3429 symbol rate:

EQM3429Table		
If EQM > than ##,## (below) [HighByte,MidByte (Hex)]	Choose this Receive Data Rate	By writing this hex value to 2E4h

00,2E	28.8 kbps	0C
00,00	31.2 kbps	0D*
* Value 0Dh not valid if symbol rate = 3000		

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Note: In steps 10a or 10b, 33.6 kbps (value of 0Eh) should only be selected if the symbol rate is 3429. If the average EQM is very good, yet the symbol rate is only 3200, then a maximum of 31.2 kbps should be selected (value of 0Dh). If the symbol rate is 3000, then a maximum of 28.8 kbps should be selected (value of 0Ch). If the user has limited the data rate through the rate mask to a value less than the one selected in steps 10a/b, the lower rate mask value will prevail.

Steps 10a/b select the desired receive rate and modify it just prior to the transmission of the MP sequence. The EQM windows listed may be altered as desired.

Table 14-3. ARA Values

Address (Hex)	2E3h Value (Corresponding Symbol Rate in Baud)				
	5 (3429)	4 (3200)	3 (3000)	2 (2800)	0 (2400)
3B0	20	20	20	20	20
3B1	18	18	16	10	0C

3BF	00	00	00	00	00

14.2 RETRAINS AND RENEGOTIATIONS

Retrains and rate renegotiations are handled in the same manner as in V.34 using the RTRN and RREN bits, respectively. For retrains, the EARC bit should be left on to allow the modem to select the highest rate possible under the current conditions. For rate renegotiations, the EARC bit should be turned off and the desired receive rate should be written to CONF (9Xh on client modem, CXh on server modem) followed by the setting of RREN. The rate masks may also be used. The CTS bit will turn off during the retrain or rate renegotiation process and will turn back on when completed.

The V.34 mask address at 383h/382h, which is used in V.34 mode, can still be used on the client modem when connected in K56flex but will only affect the transmit rate (the server modem's receive rate). When connecting in K56flex mode, it's preferable to use the new rate masks at 604h and 605h. These masks may also be used in V.34 and allow the user to manipulate the transmit and receive speeds independently as opposed to the 383h/382h mask which limits both the transmit and receive rate when used. Note, however, the new masks only limit the maximum data rate and do not allow the user to selectively disable data rates (see Table 14-1).

14.3 ROBBED BIT SIGNALING AND DIGITAL PAD DETECTION

The diagnostic status locations for robbed bit signaling (RBS) and digital pad detection algorithms are:

Client Modem

- 6E3h RBS pattern detected before pad (bits 0-5).
- 6E4h RBS pattern detected after pad (bits 0-5).
- 6E8h Number of robbed bits per frame of 6.
- 6E9h Receive data rate drop due to RBS.
- 6EAh RBS pattern detected (bits 0-5) (6E3h ORed with 6E4h).
- 6F3h Digital pad detection.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Server Modem

6ECh Number of robbed bits per frame of 6.
6EDh Receive data rate drop due to RBS.
6EEh RBS pattern detected (bits 0-5).

Definitions

Number of robbed bits per frame of 6 - Indicates the number of robbed bits detected for every 6 bytes of PCM data. Value is valid when RSLD = 1 or at completion of a retrain (CST = 1).

Receive data rate drop due to RBS - Depending on the number of bits robbed per every 6 bytes, the receive data rate will automatically be reduced. This data rate reduction value is reported as 02h, 04h, 06h or 08h for 2k, 4k, 6k or 8k bps. The robbed bit signaling does not affect the EQM readings used during phase 4 for the data rate selection. The host should select the data rate based on EQM as always. Upon connecting, the true connect speed will be the host selected speed shown in 2E4h (or CONF value) minus the data rate drop due to RBS as shown in 6E9h (client) or 6EDh (server).

As an example: EQM measurements during phase 4 indicate a 50k bps data rate should be selected. The host therefore writes 0Ah in 2E4h. When RLSD = 1, the host checks either 2E4h or CONF to confirm the selected rate and then checks the data rate drop due to RBS in 6E9h (client) or 6EDh (server). If the data rate drop indicates 04h, then the receive data rate is actually 50k - 4k or 46k bps, which is what should be reported as the connect message.

The host should not write a 2E4h data rate value higher than indicated by EQM, no matter what the rate loss due to RBS is. Both the reduction due to RBS and the host data rate limit then need to be considered.

Other examples with the AT+MS command (host limited speeds):

Ex: +MS = 40000, 46000, EQM indicates 50k possible:

If loss due to RBS were 0k, write CONF=46k and print 46k
If loss due to RBS were 2k, write CONF=48k and print 46k
If loss due to RBS were 4k, write CONF=50k and print 46k
If loss due to RBS were 6k, write CONF=50k and print 44k

Same +MS but EQM indicates 44k possible:

If loss due to RBS were 0k, write CONF=44k and print 44k
If loss due to RBS were 2k, write CONF=44k and print 42k
If loss due to RBS were 4k, write CONF=44k and print 40k
If loss due to RBS were 6k, fallback to V.34 because actual data rate is less than indicated by EQM.

In other words the EQM speed - the RBS data rate loss = the max possible speed within the limits of the +MS setting. If the resulting true speed is less than the lowest +MS setting, fallback to V.34.

Any fall forward or fallback decisions during a K56flex connection should continue to be based on the EQM value at 810h and the requested data rate value in 2E4 should be increased or decreased from its current value. The purpose of the "data rate drop due to RBS" value is for reporting the actual speed in the connect message. It does not affect the data rate selection process. This value is valid when RSLD = 1 or at completion of a retrain (CST = 1).

RBS pattern detected - Robbed bit signaling systems may rob one least significant bit from one byte out of every 6 bytes of data. If the signal is routed through more than one robbed bit system, there can potentially be more than one bit robbed per every 6 bytes. The RAM Downloadable devices can handle up to 6 robbed bits per 6 bytes (typically, no more than 1-3 bits are robbed in total on a given call). The modem detects the number a robbed bit per 6 bytes and indicates the pattern in the 6 lower bits of the addresses shown above. A value of 05h (0000 0101) would indicate that 2 bits are being robbed out of every 6 bytes and that the first and third bytes were the bytes with the robbed bit. The pattern itself has no real significance other than for testing purposes. The number of bits set in the lower 6 bits of this value simply indicates the total number of robbed bits out of every 6 bytes. The total number of set bits should correspond to the "number of robbed bits" value in 6E8h (client) and 6ECh (server). The difference is that the RBS pattern value is available when SECTXB>40h.

Digital pad detection - Bit 7 = 1 indicates 6 dB pad, bit 6 = 1 indicates 3 dB pad, and bits 7 and 6 = 0 indicates no digital pad. This value is available when SECTXB>40h. This value is used for information only.

Bit 7 = 1 indicates 6 dB pad, bit 6 = 1 indicates 3 dB pad and bits 7 and 6 = 0 indicates no digital pad. This value is available when SECTXB>40h. This value is used for information only.

15. V.90 PROGRAMMING INFORMATION

This section describes V.90 programming information for the following DSP (SPX) devices (see Table 15-1):

- L8570 and L8771 (APCM Client)
- L8565, L8765, and P8865 (DPCM Server)

The L8771 is used in R6764-2X, R6764-6X, and R6785-2X devices.

- The L8570, L8565, L8765, and P8865 uses RAM codes labeled "47.XX".
- The L8771 uses RAM codes labeled "HCF.XX".

The control of V.90 is the same for both sets of code (47.XX and HCF.XX); however, different RAM modules are downloaded.

The information and examples in this section apply to the following RAM codes:

- L8565, L8765, and P8865: 47.22
- L8570: 47.24
- L8771: HCF.24

Consult the latest release notes for current information.

Table 15-1. MDP DSP (SPX) Devices Supporting V.90

15.1 V.90 CONTROL BITS

15.1.1 6A3h:0-7 - V.90 Host Control

Bit	7	6	5	4	3	2	1	0
Function	Reserved	K56flex negotiated via V8bis 0 = N 1 = Y	Allow K56Plus 0 = N 1 = Y	Reserved	Digitally Connected 0 = N 1 = Y	APCM Capable 0 = N 1 = Y	DPCM Capable 0 = N 1 = Y	V.90 Enable 0 = N 1 = Y

Client General Procedure

- Write the desired receive rate and select V.90 mode to 6A2h (see 15.1.2).
- Select the basic V.90 control in address 6A3h:
 - Set bit 0 to 1 to enable V.90 (defaults to 1 on HCF RAM codes only).
 - Clear bit 1 to 0 to indicate **not** DPCM capable.
 - Set bit 2 to 1 to indicate APCM capable (defaults to 1 on HCF RAM codes only).
 - Clear bit 3 to 0 to indicate **not** digitally connected.
- V.90 mode requires the GSTN octet be sent in V.8 by both Client (APCM) and Server (DPCM) as follows:
 - Set bit 4/304h in both V.90 answer and originate modes.
- Set bit 6/6A3h and 0/406h to inform the data pump that K56flex has been successfully negotiated in V.8bis. This replaces the need for forcing K56flex mode during V.8 as with previous K56flex codes.
- Enabling V.90 mode (0/6A3 = 1) overrides K56flex if V.90 is negotiated in V.8. Bit 0/406h will be automatically turned off.
- Set NEWC after modifying location 6A3h.

Server General Procedure

- Write the desired receive rate and select V.90 mode to 6A2h (see 15.1.2).
 - Select the basic V.90 control in address 6A3h:
 - Set bit 0 to 1 to enable V.90.
 - Set bit 1 to 1 indicate DPCM capable.
 - Clear bit 2 to 0 to indicate **not** APCM capable.
 - Set bit 3 to 1 to indicate digitally connected.
 - V.90 mode requires the GSTN octet be sent in V.8 by both Client (APCM) and Server (DPCM) as follows:
 - Set bit 4/304h only if in V.90 originate mode. When answering, the Server will automatically send the GSTN octet only if received from a Client.
 - Set bit 6/6A3h and 0/406h to inform the data pump that K56flex has been successfully negotiated in V.8bis. This replaces the need for forcing K56flex mode during V.8 as with previous K56flex codes. If K56plus mode is a desired supported mode on the Server (not available on Client), clear bit 6/6A3h then set both bit 5/6A3h and 0/406h. This will allow the older K56plus PN+ID to be sent in the answer tone and allow the Server to proceed in K56plus mode if a K56plus Client responds. If bit 6/6A3h is also set, the K56plus PN+ID will not be sent and K56flex will be enabled.
 - Enabling V.90 mode (0/6A3 = 1) overrides K56flex if V.90 is negotiated in V.8. Bit 0/406h will be automatically turned off.
- Note:** To force K56flex on the Server, turn off bits 0 and 3 of 6A3h and set 6/6A3h and 0/406h.
- Set NEWC after modifying location 6A3h.

15.1.2 6A2h:0-7 - Desired V.90 Receive Speed

Bit	7	6	5	4	3	2	1	0
Function	Forced 1	Forced 1	V.90 Mode 0 = N 1 = Y	Receiver Speed				

Client Basic Procedure To Force a Desired Receive Rate

- Write the desired Client APCM CONF (RX Speed) from Table 15-2 to 6A2h, where:
 - Bits 0-4 select the Client receiver speed (01h-16h from four least significant bits of APCM CONF)
 - Bit 5 is set to 1 to select V.90 mode.
 - Bits 6 and 7 are set to 1.
- If V.8 successfully negotiates V.90, then the contents of 6A2h will be transferred by the data pump to the CONF register.
- Select V.90 basic control in address 6A3h (see 15.1.1).

Note: When in V.90 mode (bit 5, CONF = 1), the SPEED bits of the Client APCM modem indicate the upstream V.34 transmit rate. The SPEED bits and CONF value may be used to determine transmit and receive rates.

Server Basic Procedure To Force a Desired Receive Rate

- Write the desired Server DPCM CONF (RX Speed) from Table 15-2 to 6A2h, where:
 - Bits 0-4 select the Server receiver speed (01h-0Dh from four least significant bits of DPCM CONF).
 - Bit 5 is set to 1 to select V.90 mode.
 - Bits 6 and 7 are set to 1.
- If V.8 successfully negotiates V.90, then the contents of 6A2h will be transferred by the data pump to the CONF register.
- Select V.90 basic control in address 6A3h (see 15.1.1).

Note: When in V.90 mode (bit 5, CONF = 1), the SPEED bits of the Server DPCM modem indicate the downstream V.90 transmit rate. The SPEED bits (bits 0-4 of interface register 0Eh) will be formatted in a manner similar to the CONF register on the APCM side.

*Note: Addresses 2E5h and 2E4h can also be used to indicate the transmit and receive rates, respectively, after RLSD = 1 or after a retrain or rate renegotiation process.							

15.1.3 6C1h, 6C2h, 6C3h - Server DPCM Transmit Data Rate Mask

These DPCM Server addresses hold the DPCM to APCM transmit data rate mask for V.90 mode only. They control the data rate mask sent in the Jd sequence. They may be written to anytime prior to phase 3. The range of rates are shown in Table 4-8.

The APCM Client will receive this information and record it using the same format in the same locations 6C1h-6C3h. These locations should not be written to on the APCM Client modem.

Table 15-3. Server DPCM Transmit Data Rate Mask

Address and Rate (bps)	Bit

54667	0	0	X	1	X	X	X	X
56000	0	0	1	X	X	X	X	X

15.1.4 382h, 383h - Client APCM Transmit Data Rate Mask and Server DPCM Receive Data Rate Mask

These addresses hold the APCM to DPCM transmit data rate mask when used on the APCM Client or the DPCM receive data rate mask when used on the DPCM Server. They control the data rate mask sent in the CP and MP sequences. Setting NEWC after changing these locations causes them to be copied into addresses 112h and 113h. Since NEWC is required when writing the mask to 383h and 383h, the mask must be configured prior to the beginning of handshake. If it is desired to change the rate mask on the fly during handshake, prior to phase 4, the mask may be written directly to addresses 112h and 113h. Do not alter bit 7 of 113h; this bit controls the asymmetric setting for V.34.

The format is as follows (see Table 15-4):

- 382h APCM TX or DPCM RX rate mask: bits 1-7 = 4.8K - 19.2K (bit 0 = 2.4K for V.34)
- 383h APCM TX or DPCM RX rate mask: bits 0-4 = 21.6K - 31.2K (bit 5 = 33.6K for V.34)

The APCM transmit data rate mask may also be used in V.34 **or** K56 mode. The DPCM receive data rate mask may also be used in V.34 mode but **not** in K56 mode. Note that in V.34, these mask addresses limit both the transmit and receive rates when used in either Client or Server modems.

Note: There is no receive data rate mask on APCM Client in V.90 mode. The CP sequence sent only specifies the desired rate, not a list of rates.

Table 15-4. Client APCM Transmit Data Rate Mask and Server DPCM Receive Data Rate Mask

Address and Rate (bps)	Bit							
382h: APCM TX Rate/DPCM RX Rate	B7	B6	B5	B4	B3	B2	B1	B0

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

15.1.5 604h - APCM and DPCM Maximum Receive Data Rate

The receive rate on both the DPCM Server and APCM Client may be limited through this address. This mask may be changed anytime prior to phase 4. The maximum rate options are shown in Table 15-5.

Note: The maximum transmit data rate limit in address 605h is only available in K56 and V.34 modes and does not influence V.90 mode.

Table 15-5. APCM and DPCM Maximum Receive Data Rate

Address 604h (hex)	V.90 Mode		K56flex Mode		V.34 Mode	
	APCM Max. Speed (bps)	DPCM Max. Speed (bps)	APCM Max. Speed (bps)	DPCM Max. Speed (bps)	APCM Max. Speed (bps)	DPCM Max. Speed (bps)

15.1.6 6B3h - DPCM TX Level Control

Bit	7	6	5	4	3	2	1	0
Function	Reserved	Reserved	Measurement Point 0 = Tx Output 1 = Codec	Max Tx Power				

Format

- Bits 0-4 indicate Max TX power in 0.5 dB steps, from -0.5 dB0 to -16 dB0
- Bit 5 indicates measurement point (1 = codec, 0 = TX output)
- Bits 6-7 are reserved

Default value is 37h, which equals -12 dBm0 measured at the codec. A value of 2Bh = -6 dBm0.

15.1.7 680h:5 - Rate Renegotiation with Silence for V.90 (Fast Retrain)

To initiate a rate renegot with silence (fast retrain) in V.90 mode, set bit 5/680h followed by the RTRN bit. To initiate a normal retrain request, clear bit 5/680h followed by the RTRN bit. The fast retrain may be initiated by the APCM Client only. This bit does not apply on the DPCM Server. The renegot with silence is detected as a normal renegot by the Server. The RREDT bit will set.

The application for a rate renegotiation with silence is for situations where the echo characteristics change due to temperature changes within the Client modem. In a V.90 connection, the Client's echo canceller cannot handle the changes in echo which often occur after the modem has just been powered up. The EQM values during the first few minutes of the connection can often continue to rise as the temperature increases. This effect traditionally causes the host to request fallbacks until the EQM settles. The conventional rate renegot does not allow the echo canceller to update, however, the new renegot with silence does allow it to update. If the host notices a continuous rise in EQM after connecting, it may request the data pump to initiate a renegot with silence at the current data rate. If the EQM drops back down to an acceptable value, then a fall back is not necessary. Occasional renegs with silence may be needed during the first few minutes of the connection until the temperature stabilizes.

15.1.8 6EAh:0-5 - RBS Pattern

The RBS pattern may be read in bits 0-5 of address 6EAh. The number of bits set equals the number of robbed bits on the channel. This address applies to both V.90 and K56flex modes. Unlike K56flex mode, the data rate reported in V.90 mode through CONF, SPEED or addresses 2E5h/2E4h is the true data rate, regardless of the number of robbed bits. A data rate correction factor for RBS is subtracted only in K56flex mode.

15.1.9 39Bh:7 - A-law / u-Law Selection

Bit 7/39Bh controls the A-Law / u-Law selection. When set, A-law is enabled. When reset, u-Law is enabled (default).

The DPCM Server needs to setup this bit appropriately in all modes. In V.90 mode, an APCM Client will detect this selection through the received INFO0d sequence and automatically configure itself accordingly. As before, when in K56flex mode, the Client must setup bit 7/39Bh to the appropriate mode. This bit requires NEWC be set.

15.1.10 6C9h - Digital Loss Estimate

The amount of digital loss may be read on the Client APCM or Server DPCM modem from address 6C9h (16 bits). The format is:

$$20 * \log_{10}(N/2000h)$$

Where: N is the value read from 6C9h.

Values of approximately 2000h, 2D6Ah and 3F07h reflect digital pads of 0 dB, 3 dB and 6 dB, respectively. This value is available in phase 4 and applicable to u-Law connections only.

15.2 V.90 DATA RATE SELECTION

15.2.1 General Procedure

The procedure for selecting data rates in K56 and V.34 modes is to disable the ARA feature and have the host sum EQM samples during phase 4, after which an EQM lookup table is used to select the best data rate.

The procedure for selecting the Server rate (upstream rate) in V.90 mode is the same as when in K56 mode.

The procedure for selecting the Client rate (downstream rate) in V.90 mode is similar and is described as follows:

1. Turn off EARC.
2. Wait until SECRXB = 62h; this will occur approximately 1.6 seconds before event in step 3 occurs.
3. Wait until the LSB of 276h = 0Eh (this is the MSB value of a 16-bit count-down counter at 276h/275h).
4. Read and sum 50 (50 decimal) samples of EQM from 20Ch.
5. Discard the lower byte of EQM sum (keep the mid byte and high byte).
6. Read RBS pattern from 6EAh and determine number of RBS.
7. If RBS count is 0-1, do not subtract from Table 15-6.
8. If RBS count is 2-3, subtract 1 speed from rate table below (28.0K minimum).
9. If RBS count is 4-5, subtract 2 speeds from rate table below (28.0K minimum).
10. If RBS count is 6, subtract 3 speeds from rate table below (28.0K minimum).
11. Obtain average of 16-bit values from A62h, A61h and A60h.
12. Divide value from A63h by average value calculated in the previous step, i.e., $A63h / [(A62h + A61h + A60h) / 3]$.
13. If ratio is 6 or greater, subtract 1 more speed (28.0K minimum) to estimate the disturbance due to IMD.
14. Write the corresponding speed value in 2E4h. This must be done when counter at 276h/275h is between 0FFFh and 0C00h. There is approximately 90ms between the count value of 0EFFh obtained in step 3 and the value of 0C00h.

15.2.2 Data Rate Vs EQM Sum

Table 15-6 shows the V.90 rates versus permissible EQM. The EQM_H is the **suggested** upper limit and the EQM_L is the suggested lower limit of the EQM sum (lower byte thrown out) for the corresponding data rate.

Table 15-6. V.90 Data Rates vs. EQM Sum

Speed (bps)	EQM_H	EQM_L	2E4h
28.0K	154h	151h	01h
29.3K	150h	14Fh	02h
30.7K	14Eh	145h	03h
32.0K	144h	13Dh	04h
33.3K	13Ch	139h	05h
34.7K	138h	135h	06h
36.0K	134h	12Ah	07h
37.3K	129h	120h	08h
38.7K	11Fh	11Ah	09h
40.0K	119h	106h	0Ah
41.3K	105h	FBh	0Bh
42.7K	FAh	F6h	0Ch
44.0K	F5h	E8h	0Dh
45.3K	E7h	D8h	0Eh
46.7K	D7h	D0h	0Fh
48.0K	CFh	BDh	10h
49.3K	BCh	B1h	11h
50.7K	B0H	91h	12h
52.0K	90h	81h	13h
53.3K	80h	71h	14h
54.7K	70h	51h	15h
56.0K	50h	0h	16h

Note: It is recommended that the host monitor the frequency of data frame retransmission requests in LAPM on the Client in V.90 and K56 modes. High levels of IMD can cause frequent errors while not greatly affecting EQM readings. In order to improve throughput, the host may wish to fallback in data rate if too many retransmissions are being requested.

15.2.3 EQM Readings

As in K56flex mode, the EQM readings during V.90 data mode on the APCM Client are taken from address 810h. The scaling is roughly the same as in K56flex mode, where values around 1C00h-2500 are optimal. U-law and A-law readings may differ slightly.

The data mode EQM readings on the DPCM Server may be read from 810h as well, or the traditional 20Ch location which is still used for the EQM readings during the handshake or retrains. Both locations give the same data mode readings on the DPCM Server.

As usual, the EARC bit should be turned off prior to forcing a rate change.

15.2.4 Forcing a V.34 Fallback From V.90

If the Client EQM readings in phase 4 are not acceptable, the host may abort the V.90 handshake or retrain attempt and force a V.34 fallback by clearing bits 0/401h and 0/6C0h. Set 6/13Fh to allow asymmetric data rates.

Note: A fallback to V.34 from V.90 will always result in a V.34 originate mode handshake sequence from the Server and a V.34 answer mode handshake sequence from the Client, no matter which modem answered or originated the call to begin with. In other words, the ORG bit will always read back as a 1 on the Server and a 0 on the Client. Implement any V.34 workarounds according to the ORG bit status.

16. RAM DOWNLOAD AND V.90/K56FLEX BIMODAL SETUP

16.1 RAM DOWNLOAD MODULES

The Server L8565 Device RAM download supports both K56flex (K56) and V.90.

The Client L8570 and L8771 Device RAM download currently only supports V.90 and requires a download of existing K56 modules as described in following procedures. Consult the latest release notes for current information.

16.1.1 Server V.90 RAM Code

Server L8565 Controller File: 47.XX V.90/K56 Code

The **Server L8565 Controller** file has the following modules in the 47.XX **V.90/K56** codes:

- Ram_Intercept_Vectors
- V8x_Ram_code
- Vfc_Ram_code
- K56_Ram_code
- Vpcm_Ram_code
- PCM_Common_Ram
- PorInit_Ram_code
- Common_Ram_code
- **VPCM_Mem_Holder** - Spaceholder, do not download!!
- **Ram_File_Header** - Contains the Ram file information, do not download!!

Server L8565 Spx File 47.XX V.90/K56 Code

The **Server L8565 Spx** file has the following modules in the 47.XX **V.90/K56** codes:

- B0_Ram_code_vectors
- Baud_Ramcode
- Encoder_Ramcode
- PcmTx_Ramcode
- PcmRom_Ramcode

16.1.2 Client V.90 RAM Code

Client L8570 Controller File: 47.XX V.90 Code

The **Client L8570 Controller** file has the following modules in the 47.XX **V.90** codes:

- Ram_Intercept_Vectors
- V8x_Ram_code
- SPK_RAM_code
- VFC_Ram_code
- Vpcm_Ram_code
- PCM_Common_Ram
- PorInit_Ram_code
- Common_Ram_code
- DownDefVec_Ram_code
- **VPCM_Mem_Holder** - Space holder, do not download!!
- **Ram_File_Header** - Contains the Ram file information, do not download!!

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Client L8570 Spx File: 47.XX V.90 Code

The Client L8570 Spx file has the following modules in the 47.XX V.90 codes:

- B0_Ram_code_vectors
- Baud_Ramcode
- Encoder_Ramcode
- PcmRx_Ramcode
- PcmRom_Ramcode
- General_DownloadCode
- V61_Ramcode
- Spkphone_Ramcode

Client L8771 Controller File: HCF XX V.90 Code

The Client L8771 Controller file has the following modules in the HCF XX V.90 codes:

- Ram_Intercept_Vectors
- V8_FSK_Ram_code
- V34F_RAM_code
- V34_RAM_code
- SPK_RAM_code
- VFC_Ram_code
- AVPCM_Ram_code
- General_Ram_code
- PorInit_Ram_code
- Voice_Ram_code
- DownDefVec_Ram_code
- Ram_File_Header - Contains the Ram file information, do not download!!

Client L8771 Spx File: HCF XX V.90 Code

The Client L8771 Spx file has the following modules in the HCF XX V.90 codes:

- B0_Ram_Code_Vectors
- General_Ram_code
- Voice_Ramcode
- APCM_Common_Ramcode
- AVPCM_Ramcode
- AK56_Ramcode
- ASPK_Ramcode
- EC_Ramcode
- DSPK_Ramcode
- DL_EXE0_Vectors - Do not download!!
- DL_EXE1_Vectors - Do not download!!

16.1.3 Client K56flex RAM Code

The modules marked with ** are needed for a K56flex connection. Other modules from these RAM files should be discarded. For modes such as speakerphone and VFC, the modules in the V.90 RAM codes should be used.

The Ram_Intercept_Vectors must be the last CTL module loaded and the B0_Ram_code_Vectors must be the last Spx module loaded.

Client L8570 Controller File: Version 47 K56-only Code

The Client L8570 Controller file has the following modules in Version 47 K56-only code:

- **Ram_Intercept_Vectors (this module must be loaded last in this series)
- SPK_RAM_code
- VFC_Ram_code
- **K56_Ram_code
- **General_Ram_code
- **Modes_Ram_code

Client L8570 Spx File: Version 47 K56-only Code

The Client L8570 Spx file has the following modules in Version 47 K56-only code:

- **B0_Ram_code_Vectors (this module must be loaded last in this series)
- **Baud_Ramcode
- **Encoder_Ramcode
- **PcmRx_Ramcode
- **PcmRom_Ramcode
- V61_Ramcode
- Spkphone_Ramcode

Client L8771 Controller File: HCF 7.1 K56-only Code

The Client L8771 Controller file has the following modules in the HCF 7.1 K56-only code:

- **Ram_Intercept_Vectors (this module must be loaded last in this series)
- V34F_RAM_code
- **K56_RAM_code
- SPK_RAM_code
- VFC_Ram_code
- **General_Ram_code

Client L8771 Spx File: HCF 7.1 K56-only Code

The Client L8771 Spx file has the following modules in the HCF 7.1 K56-only code:

- **B0_Ram_Code_Vectors (this module must be loaded last in this series)
- **Voice_Ramcode
- **PCMRX_Ramcode
- ASPK_Ramcode
- EC_Ramcode
- DSPK_Ramcode
- DL_EXE0_Vectors - Do not download!!
- DL_EXE1_Vectors - Do not download!!

16.2 RAM MODULE DOWNLOAD PROCEDURE

The L85xx Downloadable Datapump contains 2 SRAM sections:

1. Section for Control Code, called the CTL SRAM.
2. Section for DSP Code, called the SPX SRAM.

16.2.1 Downloading can be initiated by the Host or the Datapump

Host Request Download

Before setting NEWC to configure to a new mode, the host may initiate a download to the datapump (MDP). For example, after POR, or hardware reset, or software reset, the host would load the startup modules required to initiate a connection attempt. NOTE: if the datapump detects that required modules are not in the SRAM, the datapump will request a download from the host by presenting the module ID in the ABCODE register.

Datapump Request Download

During a connection sequence, when the modules in SRAM are not correct for the connection type, the datapump will request a download from the host. For example, if the datapump SRAM is loaded with modules for V.90, but the connection type selected is V.FC, then the host must download the module for V.FC at the request of the datapump, before the connection sequence can continue.

Only the code necessary to run the selected mode is required to be in the SRAM, but code for other modes can also be in SRAM, at the same time, as long as they do not overlap the same SRAM address space. The starting and ending address for each RAM module is included in the RAM files.

The RAM modules must be downloaded in the order specified in the Release Notes for the RAM files.

The datapump ROM contains code, which is common to all modes, and code for the following specific modes: V.32bis, V.22, V.17, V.29, V.27, V.8 and all FSK modes.

The RAM_Intercept_Vectors table is initialized with the ROM default values following a POR, Hardware Reset, or Software Reset.

Code Download Time Estimates

Assuming the host microprocessor is running faster than the datapump (i.e., the datapump is never waiting for the host to download a data byte), the time to download 12K bytes into the Controller (CTL) section of the SRAM, is about 14.5 ms (plus some small handshake overhead), and the time to download 12K bytes into the DSP (SPX) section of the SRAM, is about 11.3 ms. Therefore, the total time to download the datapump is typically less than 60 ms.

Download Protocol

The download protocol uses datapump Interface Memory (Scratchpad) Register ABCODE (14h:0-7) and a 2-byte RAM address register called RAM_adrcnt (MSB uses SECTXB 17h:0-7, and LSB uses SECRXB 16h:0-7). The host can request a download to SRAM anytime by writing a request to download into ABCODE, and the datapump can also request a download by writing a request to ABCODE which is the module ID as it appears in the RAM file. The definitions for ABCODE download requests from the host are listed below:

4Fh	Host requests download to CTL SRAM, then return. This request is used before configuring to a new mode
5Fh	Host requests download to SPX SRAM.

16.3 DOWNLOAD FILE FORMAT

Modules for the CTL SRAM section and modules for the SPX SRAM section are contained in 2 separate binary files.

Server Files are: SCTL###.RAM and SSPX###.RAM

= Revision Number

Client Files are: CCTL###.RAM and CSPX###.RAM

= Revision Number

All RAM files have the same binary file format.

The following conventions are used:

byte	8-bits
word	16-bits, LSB first, MSB last
dword	32-bits, LSB first, MSB last
ASCII	sequence of bytes, terminated with a byte of zero

The 1st byte of the RAM file is byte number 0 (zero).

The RAM file starts with an 8 byte header which has the format:

4 bytes	'DRAM'	indicates a RAM download file
1 word	version	the version number of the RAM file (e.g., 51h)
1 word	nram	no. of RAM descriptors following

Following the header are the RAM module descriptors which have the following format:

1 word	mod	RAM module ID byte
1 word	id	RAM download ID byte
1 word	type	CTL download (0000) or SPX download (8000h)
1 byte	crc	8-bit crc code for the data module
1 byte		reserved
1 dword	start	starting address for download
1 dword	end	ending address for download
1 dword	len	length of data to download

NOTE: len is # of bytes for the CTL.RAM file, and # of DWORD's for the SPX.RAM file.

1 dword	pos	offset of 1 st data byte (from start of the RAM file)
1 dword	next	offset to next descriptor (from start of the RAM file)
asciiz	name	name of the section which contains the data

The CRC is calculated as follows:

```
byte crc,*p;
dword l;
for(crc=0,p=file[pos],l=len;l--:p++)
    crc=(crc<<1)+((crc&0x80)>>7)+*p;
```

16.3.1 RAM File Header Information

The V.90 RAM files now contain a module called Ram_File_Header. This module is not downloaded but points to a location in the file where the header information begins. The following is an example header from the controller file for the L8570 client device:

(c)Rockwell:04-Feb-1998:L8570A:CTL:47084701

All information except the last 4701 is in ASCII. The 47 and the 01 are in hex and represent the flex and pcm version respectively. The 4708 represents the file version, CTL means this is the CTL file (note: only the CTL files contain the header), the L8570A is the device (it would be L8565A for the server) and the remaining information is self explanatory.

Note: The Ram_File_Header module is not available in the K56flex-only RAM code.

Host Request Download Procedure

1. After POR, hardware reset, or software reset, the datapump automatically loads the default values into the Vector_Table, and clears SRAM addresses 1400h and 3000h.
2. To load modules into the datapump, the host requests a download as follows:
3. The host writes ABCODE = 4Fh (14h:0-7) for CTL download or 5Fh for SPX download. Note: download order can be CTL before SPX, or SPX before CTL.
4. The host waits for the datapump to acknowledge it is ready, by reading Scratchpad Register 1Bh. The datapump will copy the contents of ABCODE into Scratchpad Register 1Bh when it is ready to accept data.
5. The host writes the 2-byte starting address, from the RAM module descriptor in the RAM file, into RAM_adrcnt (MSB in SECTXB 17h:0-7, and LSB in SECRXB 16h:0-7). **NOTE:** write LSB Byte FIRST. There is a 30 second timeout before the datapump aborts the download by resetting ABCODE=00.
6. The host reads each byte from the selected module in the RAM file and writes them to TBUFFER, while the TXFNF bit is 1 (0Dh:1). During download, Scratchpad Register 1Bh is continuously updated with the DMA buffer status, but the host should use the FIFO TXFNF bit because the DMA buffer is just an extension of the FIFO.
7. After the last byte for the selected module is written to TBUFFER, the host writes ABCODE = 00.
8. The host then waits for Scratchpad register 17h to be FFh and reads the CRC byte from Scratchpad address 16h. If the CRC value matches the CRC byte in the RAM file for the selected module, the module was correctly downloaded. If the CRC does not match, the host should issue a Reset (either Hardware or Software), and repeat the Download Procedure. After a module download, the datapump restores the contents of Scratchpad Register 1Bh, and resumes normal operation. Scratchpad registers 16h and 17h are not restored.
9. If there is another module to download, then the host repeats the download procedure, beginning at step 1, by writing ABCODE = 4Fh or 5Fh. There is a 30-second timeout for the host to write to ABCODE before the modem aborts the download. The datapump will clear ABCODE if it decides to abort the download.
10. The host can now set CONF, and NEWC=1, to configure the datapump to a mode supported by the downloaded modules.
11. The host must avoid downloading a set of modules that overlap in the SRAM address space. Also, the host must update the Vector_Table to contain only the modules currently loaded in SRAM.
12. When the host requests a download, the datapump will overwrite the SRAM specified by the host, without checking Module IDs.

Datapump Request Download Procedure

After the host sets NEWC=1, or during a V.8 sequence or during automode, the datapump will check the mode ID in RAM. If the mode specified in the CONF Register is not present in SRAM, the datapump will request the host to download the appropriate modules, before attempting to connect in that mode. Also, if the host changes the CONF register to a mode that is not present in SRAM, the datapump will request the host to download the required modules. The following procedure describes the datapump requesting a host download:

The datapump completes the V.8 or automode sequences, and determines the required configuration. If the current Vector_Table does not support the required configuration, the datapump initiates a download request, as follows:

1. The datapump initializes RAM_adrcnt to FFFFh and writes the appropriate download request into ABCODE.
2. The host reads the ABCODE value, and locates the requested module in the appropriate RAM file.
3. The host writes the 2-byte starting address for the requested module into RAM_adrcnt (MSB in SECTXB 17h:0-7, and LSB in SECRXB 16h:0-7). **NOTE:** write LSB Byte FIRST. There is a 30 second timeout before the datapump aborts the download by resetting ABCODE = 00.
4. The host reads each byte from the selected module in the RAM file and writes them to TBUFFER, while the TXFNF bit is 1 (0Dh:1). During download, Scratchpad Register 1Bh is continuously updated with the DMA buffer status, but the host should use the FIFO TXFNF bit because the DMA buffer is just an extension of the FIFO.
5. After the last byte for the selected module is written to TBUFFER, the host writes ABCODE = 00.
6. The host then waits for Scratchpad register 17h to be FFh and reads the CRC byte from Scratchpad address 16h. If the CRC value matches the CRC byte in the RAM file for the selected module, the module was correctly downloaded. If the CRC does not match, the host should issue a Reset (either Hardware or Software), and repeat the download procedure. After a module download, the datapump restores the contents of Scratchpad Register 1Bh, and resumes normal operation. Scratchpad registers 16h and 17h are not restored.
7. If, the datapump requires another module to be downloaded, it will request the appropriate module by writing a new ID number in ABCODE.

16.4 RAM DOWNLOAD PROCEDURES

On the Server L8565 device, the SPX Program RAM is downloaded once after POR or soft reset and is not downloaded again until the next reset. Only the Controller Program RAM modules are changing depending on the modes selected.

The Client L8570 and L8771 RAM download currently only supports V.90 and V.34. If K56 is selected, the Host must download K56 RAM Update Version 47 (or desired version) for the L8570 or HCF 7.1 for the L8771 into both the SPX and Controller.

After a reset, the host downloads the necessary modules to support V.8 mode. After V.8, depending on the mode selected, the modem will request the necessary modules for each mode.

Initial RAM Download for Data Modes: Server or Client L8570 and L8565

After Reset

1. Download into the Controller the following V.90 code startup modules:
 - Common_Ram_code
 - DownDefVec_Ram_code **(available in Client codes only)**
 - PORInit_Ram_code
 - V8x_Ram_code
 - Ram_Intercept_Vectors **(this module must be loaded last in this series)**
2. Then, download into the SPX the following V.90 code modules:
 - Baud_Ramcode
 - Encoder_Ramcode
 - PcmTx_Ramcode (for L8565 server) PcmRx_Ramcode (for L8570 Client)
 - PcmRom_Ramcode
 - General_DownloadCode **(available in Client codes only)**
 - B0_Ram_code_vectors **(this module must be loaded last in this series)**

After V.8

1. If FSK, V22, any Fax mode, or V.32 is selected, no new modules need to be downloaded.
2. If V.FC is selected (server only), the modem will request the host to download **VFC_Ram_code** with ABCODE = 48h. (**V8x_Ram_code** must already be present in Ram for V.FC to function)
3. If V.34 is selected, the modem will request the host to download **PCM_Common_Ram** module into the Controller with ABCODE = 43h.
4. If V.90 is selected, the modem will request the host to download **PCM_Common_Ram** module into the Controller with ABCODE = 43h and **Vpcm_Ram_code** module with ABCODE = 4Ah.
5. If K56 is selected:
 - On the Server: The modem will request the host to download **PCM_Common_Ram** module into the Controller with ABCODE = 43h and **K56_Ram_code** module with ABCODE = 40h.
 - On the Client: The CONF will change to 00h indicating the host must download K56flex RAM Update Version 47 (or desired version) into both the Controller and the SPX.

Initial RAM Download for Data Modes: Server or Client L8771

After Reset

1. Download into the Controller the following V.90 code startup modules:
 - DownDefVec_Ram_code
 - General_Ram_code
 - PORInit_Ram_code
 - Voice_Ram_code
 - V8_FSK_Ram_code
 - Ram_Intercept_Vectors **(this module must be loaded last in this series)**
2. Then, download into the SPX the following V.90 code modules:
 - AVPCM_Ramcode
 - APCM_Common_Ramcode
 - General_Ramcode
 - B0_Ram_code_vectors **(this module must be loaded last in this series)**
3. After setting CONF = AAh and setting NEWC, the modem will request the **V34_Ram_code** module with ABCODE 49h. This module may be pre-loaded to avoid the pump requested download. If pre-loading this module, it must be done after all the above controller modules have been loaded, including the Ram_Intercept_Vectors.

After V.8

1. If FSK, V22, any Fax mode, V.32 or V.34 is selected, no new modules need to be downloaded.
2. If V.FC is selected (server only), the modem will request the host to download **VFC_Ram_code** with ABCODE = 48h. (**V8x_Ram_code** must already be present in Ram for V.FC to function)
3. If V.90 is selected, the modem will request the host to download **AVPCM_Ram_code** module into the Controller with ABCODE = 4Ah.
4. If K56 is selected, the host must reset the modem and download K56flex RAM Update HCF version 7.1 into both the Controller and the SPX.

RAM Download For Speakerphone/Voice or V.61 Mode: Client L8570

After Reset

1. Download into the Controller the following startup modules:
 - Common_Ram_code
 - DownDefVec_Ram_code
 - PORInit_Ram_code
 - SPK_Ram_code
 - Ram_Intercept_Vectors **(this module must be loaded last in this series)**
2. Then, download into the SPX the following modules:
 - General_DownloadCode
 - Baud_Ramcode
 - Encoder_Ramcode
 - Spkphone_Ramcode or V61_Ramcode (choose one mode or the other)
 - B0_Ram_code_vectors **(this module must be loaded last in this series)**

RAM Download For Speakerphone/Voice or V.61 Mode: Client L8771

After Reset

1. Download into the Controller the following startup modules:
 - DownDefVec_Ram_code
 - General_Ram_code
 - PORInit_Ram_code
 - Voice_Ram_code
 - SPK_Ram_code (not required for V.61)
 - V8_FSK_Ram_code (if desired for negotiating V.61)
 - Ram_Intercept_Vectors **(this module must be loaded last in this series)**
2. Then, download into the SPX the following modules:
 - ASPK_Ramcode
 - Voice_Ramcode
 - General_Ramcode
 - B0_Ram_code_vectors **(this module must be loaded last in this series)**

RAM Download for Digital Speakerphone (Host-based DSVD): Client L8771

After Reset

1. Download into the Controller the following startup modules:
 - DownDefVec_Ram_code
 - General_Ram_code
 - PORInit_Ram_code
 - Voice_Ram_code
 - Ram_Intercept_Vectors **(this module must be loaded last in this series)**
2. Then, download into the SPX the following modules:
 - DSPK_Ramcode
 - EC_Ramcode
 - Voice_Ramcode
 - General_Ramcode
 - B0_Ram_code_vectors **(this module must be loaded last in this series)**

RAM Download for V.34 Fax: Client L8771

After Reset

1. Download into the Controller the following startup module:
 - V34F_Ram_code (this is the only module required)

16.5 TYPICAL HANDSHAKE SCENERIOS

The following are typical examples of Server and Client negotiation sequences, with the minimum configuration settings required.

16.5.1 Setup for Answering Server: V.90, K56flex, K56plus, V.34, VFC, V.32bis.....

1. Reset.
2. Download the startup modules listed above under the Standard RAM Download section.
3. Answer a call in V.8bis by sending CRe.
4. Perform V.8bis sequence if the Client responds with CRd.
5. After V.8bis is finished or the timeout waiting for CRd has expired, set CONF = AAh for V.8.
6. Set the V.90 configuration address 6A3h to 6Bh and 0/406h = 1 if K56flex was negotiated in V.8bis, or, 6A3h = 0Bh and 0/406 = 0 if K56flex was not negotiated.
7. If flex was not negotiated but K56plus is a desired fallback, clear 6/6A3h then set 5/6A3h = 1 and 0/406h = 1.
8. Turn off the GSTN octet by resetting 4/304h = 0 (will automatically be sent if Client is V.90).
9. Set the desired V.90 starting CONF value in 6A2h to Exh.
10. Set the desired K56flex/v.34 starting CONF value in 309h to Cxh.
11. Set ORG = 0, DATA = 0, AUTO = 1 and EARC = 1.
12. Set NEWC = 1, wait for it to clear and then set DTR = 1 to start the V.8 handshake.
13. If VFC is negotiated, the modem will request the VFC_Ram_code module. Skip to step 16.
14. After V.8 is finished (CONF value changes from AAh to some other value), the modem will request the host download the appropriate module(s) for V.90, K56flex/plus or V.34.
15. The negotiated handshake will automatically continue once the download is completed.
16. Proceed with workarounds, rate selection process and other routines per the mode selected.

16.5.2 Setup for Originating Server: V.90, K56flex, K56plus, V.34, VFC, V.32bis.....

1. Reset.
2. Download the startup modules listed above under the Standard RAM Download section.
3. If ANSam is detected, set CONF = AAh for V.8 and go to step 6.
4. If the Client responds with CRe, perform V.8bis sequence.
5. After V.8bis is finished or the timeout waiting for CRd has expired, set CONF = AAh for V.8.
6. Set the V.90 configuration address 6A3h to 6Bh and 0/406h = 1 if K56flex was negotiated in V.8bis, or, 6A3h = 0Bh and 0/406 = 0 if K56flex was not negotiated.
7. If flex was not negotiated but K56plus is a desired fallback, clear 6/6A3h then set 5/6A3h = 1 and 0/406h = 1.
8. Enable the GSTN octet by setting 4/304h = 1 (only in originate mode).
9. Set the desired V.90 starting CONF value in 6A2h to Exh.
10. Set the desired K56flex/v.34 starting CONF value in 309h to Cxh.
11. Set ORG = 1, DATA = 0, AUTO = 1 and EARC = 1.
12. Set NEWC = 1, wait for it to clear and then set DTR = 1 to start the V.8 handshake.
13. If VFC is negotiated, the modem will request the VFC_Ram_code module. Skip to step 16.
14. After V.8 is finished (CONF value changes from AAh to some other value), the modem will request the host download the appropriate module(s) for V.90, K56flex/plus or V.34.
15. The negotiated handshake will automatically continue once the download is completed.
16. Proceed with workarounds, rate selection process and other routines per the mode selected.

16.5.3 Setup for Originating Client: V.90, K56flex, V.34, V.32bis, with V.90 Priority over K56flex

1. Reset.
2. Download the startup modules listed above under the Standard RAM Download section.
3. If CRe is detected, perform the necessary V.8bis sequence.
4. After V.8bis is finished or answer tone has been detected, set CONF = AAh for V.8.
5. Set the V.90 configuration address 6A3h to 05h. If K56flex was detected in V.8bis and if it is a desired fallback, set 6A3h to 45h and also set bit 0/406h=1.
6. Enable the GSTN octet by setting 4/304h = 1.
7. Set the desired V.90 starting CONF value in 6A2h to Exh or Fxh.
8. Set the desired K56 starting CONF value in 409h to 00h. (See note 1.)
9. Set the desired V.34 starting CONF value in 309h to Cxh.
10. Set ORG = 1, DATA = 0, AUTO = 1 and EARC = 1.
11. Set NEWC = 1, wait for it to clear and then set DTR = 1 to start the V.8 handshake.
12. After V.8 is finished, if CONF = Exh or Fxh (V.90 mode), download the PCM_Common_Ram and Vpcm_Ram_code modules when requested by the modem with the appropriate ABCODE and then go to step 16. (Only the AVPCM_Ram_code will be requested from a L8771 device).
13. If CONF = Cxh for V.34, download the PCM_Common_Ram module when requested by the modem and then go to step 16. (no module will be requested from a L8771 device).
14. If the CONF = 00h for K56flex, download the old K56flex-only modules.
15. Set CONF = 9Dh (or specific speed if desired) without setting NEWC. The K56flex handshake will now proceed.
16. Proceed with workarounds, rate selection process and other routines per the mode selected.

16.5.4 Setup for Originating Client: K56flex, V.90, V.34, V.32bis, with K56flex Priority over V.90

1. Reset.
2. Download the startup modules listed above under the Standard RAM Download section.
3. If CRe is detected, perform the necessary V.8bis sequence.
4. After V.8bis is finished and K56flex has been negotiated, write 00h to CONF, set NEWC, download the old K56flex-only modules and then configure the modem for V.8 and force K56flex mode as done on previous K56flex versions. (Start V.8, wait for SECRXB = 2, set 0/406h.....) Skip to step 14. (See note 1.)
5. If answer tone is detected and K56flex was not negotiated, set CONF = AAh for V.8.
6. Set the V.90 configuration address 6A3h to 05h.
7. Enable the GSTN octet by setting 4/304h = 1.
8. Set the desired V.90 starting CONF value in 6A2h to Exh or Fxh.
9. Set the desired V.34 starting CONF value in 309h to Cxh.
10. Set ORG = 1, DATA = 0, AUTO = 1 and EARC = 1.
11. Set NEWC = 1, wait for it to clear and then set DTR = 1 to start the V.8 handshake.
12. After V.8 is finished, if CONF = Exh or Fxh (V.90 mode), download the PCM_Common_Ram and Vpcm_Ram_code modules when requested by the modem with the appropriate ABCODE and then go to step 14. (Only the AVPCM_Ram_code will be requested from a L8771 device).
13. If CONF = Cxh and V.34 is desired, download the PCM_Common_Ram module when requested by the modem and then go to step 14. (no module will be requested from a L8771 device).
14. Proceed with workarounds, rate selection process and other routines per the mode selected.

16.5.5 Setup for Answering Client: V.90, K56flex, V.34, V.32bis, with V.90 Priority over K56flex

1. Reset.
2. Download the startup modules listed above under the Standard RAM Download section.
3. Send CRe and perform the necessary V.8bis sequence if CRd is detected.
4. After performing V.8bis, or, after time-out expires waiting for CRd, set CONF = AAh for V.8.
5. Set the V.90 configuration address 6A3h to 05h. If K56flex was detected in V.8bis and if it is a desired fallback, set 6A3h to 45h and also set bit 0/406h=1.
6. Enable the GSTN octet by setting 4/304h = 1.
7. Set the desired V.90 starting CONF value in 6A2h to Exh or Fxh.
8. Set the desired K56 starting CONF value in 409h to 00h. (See note 1.)
9. Set the desired V.34 starting CONF value in 309h to Cxh.
10. Set ORG = 0, DATA = 0, AUTO = 1 and EARC = 1.
11. Set NEWC = 1, wait for it to clear and then set DTR = 1 to start the V.8 handshake.
12. After V.8 is finished, if CONF = Exh or Fxh (V.90 mode), download the PCM_Common_Ram and Vpcm_Ram_code modules when requested by the modem with the appropriate ABCODE and then go to step 16. (Only the AVPCM_Ram_code will be requested from a L8771 device).
13. If CONF = Cxh for V.34, download the PCM_Common_Ram module when requested by the modem and then go to step 16. (no module will be requested from a L8771 device).
14. If the CONF = 00h for K56flex, download the old K56flex-only modules.
15. Set CONF = 9Dh (or specific speed if desired) without setting NEWC. The K56flex handshake will now proceed.
16. Proceed with workarounds, rate selection process and other routines per the mode selected.

16.5.6 Setup for Answering Client: K56flex, V.90, V.34, V.32bis, with K56flex Priority over V.90

1. Reset.
2. Download the startup modules listed above under the Standard RAM Download section.
3. Send CRe and perform the necessary V.8bis sequence if CRd is detected. If time-out expires, go to step 5.
4. After V.8bis is finished and K56flex has been negotiated, write 00h to CONF, set NEWC, download the old K56flex-only modules and then configure the modem for V.8 and force K56flex mode as done on previous K56flex versions. (Start V.8, wait for SECRXB = 2, set 0/406h.....) Skip to step 14. (See note 1.)
5. If the time-out waiting for CRd expires, set CONF = AAh for V.8.
6. Set the V.90 configuration address 6A3h to 05h.
7. Enable the GSTN octet by setting 4/304h = 1.
8. Set the desired V.90 starting CONF value in 6A2h to Exh or Fxh.
9. Set the desired V.34 starting CONF value in 309h to Cxh.
10. Set ORG = 0, DATA = 0, AUTO = 1 and EARC = 1.
11. Set NEWC = 1, wait for it to clear and then set DTR = 1 to start the V.8 handshake.
12. After V.8 is finished, if CONF = Exh or Fxh (V.90 mode), download the PCM_Common_Ram and Vpcm_Ram_code modules when requested by the modem with the appropriate ABCODE and then go to step 14. (Only the AVPCM_Ram_code will be requested from a L8771 device).
13. If CONF = Cxh and V.34 is desired, download the PCM_Common_Ram module when requested by the modem and then go to step 14. (no module will be requested from a L8771 device).
14. Proceed with workarounds, rate selection process and other routines per the mode selected.

Notes:

1. The CONF value of 00h allows the modem to go back and execute from ROM, which allows the host to download any desired modules without the need to reset the modem. This feature is only available in RAM codes 47.23 or higher for L8570-based devices or HCF 21 or higher for the L8771-based devices. After the download is complete, change CONF to a valid configuration and set NEWC before performing any memory read/write operations.
2. In V.90 mode, the ORG bit will automatically set to a 1 on the server and to a 0 on the Client once in phase 2 of the V.90 handshake. In K56 mode, ORG bit will automatically reset to a 0 on the server and to a 1 on the Client once in phase 2. Do not alter the ORG bit once the V.90 or K56flex handshake is underway. If a fallback to V.34 occurs after phase 2 of an attempted V.90 or K56flex handshake, implement features or workarounds, keeping in mind the ORG bit status.

16.6 INITIAL HANDSHAKE DECISION PROCESS

This section describes the initial handshake decision process.

16.6.1 Bi-Modal Server: Answer Mode

An answering server (Figure 16-1) first sends CRe and allows for V.8bis should a K56flex-only Client call in. Whether or not V.8bis is negotiated, the server then proceeds to V.8. If the Client indicates V.90 capability in CM, the server informs the Client of its V.90 capability through V.8 as specified by V.90. If V.90 is negotiated, the modems connect in V.90 mode. However, if the Client does not indicate V.90 capability within V.8, the server proceeds with K56flex mode if negotiated in V.8bis. If K56flex was not negotiated, the server proceeds with V.34 and normal automode procedures.

Not shown is the possibility of a VFC connection. The data pump will request the VFC_Ram_code just after starting V.8 if the Client is requesting VFC.

16.6.2 Bi-Modal Server: Originate Mode

An originating server (Figure 16-2) looks for ANSam or CRe. If ANSam is detected, it proceeds with V.8. If CRe is detected, it first performs V.8bis before proceeding with V.8. The server then indicates V.90 capability through V.8 as specified by V.90. If V.90 is negotiated, the modems connect in V.90 mode. However, if the Client does not indicate V.90 capability within V.8, the server proceeds with K56flex mode if negotiated in V.8bis. If K56flex was not negotiated, the server proceeds with V.34 and normal automode procedures.

16.6.3 Bi-Modal Client: Originate Mode

An originating Client (Figure 16-3) can detect CRe or ANSam. If CRe is detected, the Client performs V.8bis and indicates K56flex capability per the K56flex specification. After V.8bis, if the user prefers K56flex over V.90 and K56flex was negotiated in V.8bis, the Client proceeds with V.8 without V.90 settings and connects in K56flex mode. If the user prefers V.90 over K56flex, or, ANSam is detected instead of CRe, the Client proceeds with V.8 and with V.90 settings as specified by V.90. If V.90 is negotiated during V.8, the modems connect in V.90 mode. If V.90 is not negotiated but K56flex was negotiated in V.8bis, the modems connect in K56flex mode. If neither V.90 or K56flex are negotiated, the modems fall back to V.34 and normal automode procedures.

16.6.4 Bi-Modal Client: Answer Mode

An answering Client (Figure 16-4) first sends CRe. If CRd is detected, the Client performs V.8bis and indicates K56flex capability per the K56flex specification. After V.8bis, if the user prefers K56flex over V.90 and K56flex was negotiated in V.8bis, the Client proceeds with V.8 without V.90 settings and connects in K56flex mode. However, if CRd is not detected, or, if CRd is detected and V.8bis is performed but the user prefers V.90 over K56flex, the Client proceeds with V.8 and with V.90 settings as specified by V.90. If V.90 is negotiated during V.8, the modems connect in V.90 mode. If V.90 is not negotiated but K56flex was negotiated in V.8bis, the modems connect in K56flex mode. If neither V.90 or K56flex are negotiated, the modems fall back to V.34 and normal automode procedures.

17. V.34 FAX OPERATIONS

This chapter discusses the operation of V.34 Fax, considering both the original V.21 procedures and the ITU-T Recommendation V.8 (hereafter V.8) based startup procedure. V.21/V.8 interoperability and the related topic, turnaround polling, are also described.

Section 17.1 discusses the theory of V.34 Fax half-duplex operations defined in ITU-T Recommendation V.34 (section 12), Recommendation V.8, and Annex F to Recommendation T.30.

Section 17.2 summarizes various start-up scenarios for fax including: automatic start, manual start, and missed signals. The scenarios are described and the associated detectors needed at each stage are identified.

Section 17.3 discusses turnaround polling scenarios.

Section 17.4 is a summary of all detectors active during a given state of operations

Section 17.5 describes modem operation during startup and turnaround polling.

Section 17.6 describes modem operation during handshake monitoring.

17.1 V.34 FAX OPERATION SPECIFICATIONS

The V.34 Fax half-duplex operation is a mode of operation wherein exchange of data alternates between unidirectional transmission of primary channel data (from source to recipient modem), and simultaneous bi-directional transmission of control channel data. The ITU-T Recommendation T.30 describes the procedures for the optional use of the half-duplex V.34 modulation system.

The V.34 half-duplex mode is used for data transmission; the duplex control channel is used in pseudo half-duplex to provide binary coded procedural data and to replace the original V.21 Channel 2. The use of ECM mode is mandatory for all facsimile messages using the V.34 modulation system. Figure 17-1 shows a typical V.34 Fax starting sequence of events.

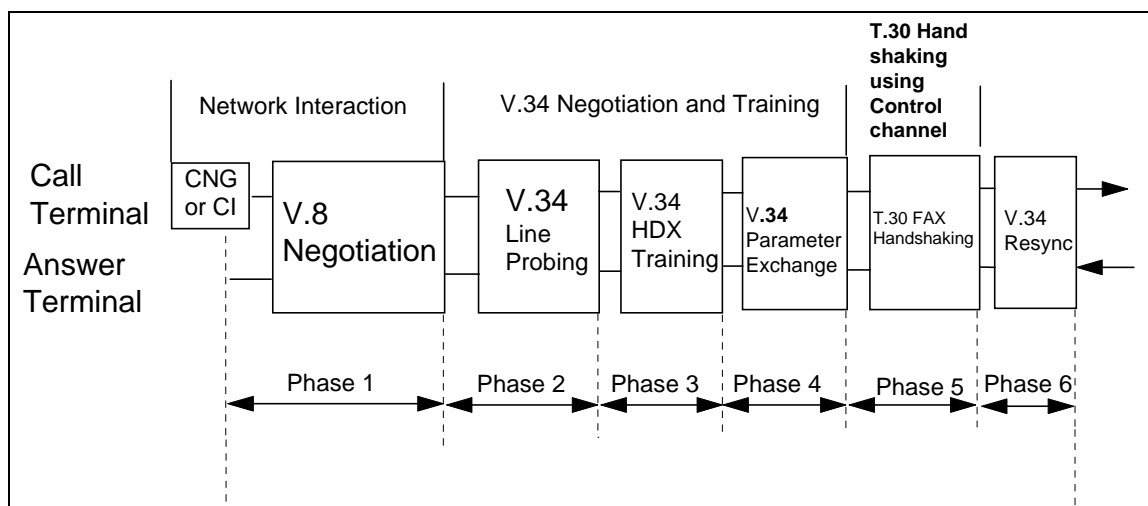

Figure 17-1. V.34 Fax Starting Sequence

In Phase 1 the new V.8 defined procedures are used for the network interaction and provide initial negotiations between two modems. Using V.21 modulation both modems provide the information on the Call function, the protocol available, the network access, and the modulation modes available.

Figure 17-2 shows the Phase 1 exchange. In Phase 2 modems perform a channel probing and ranging.

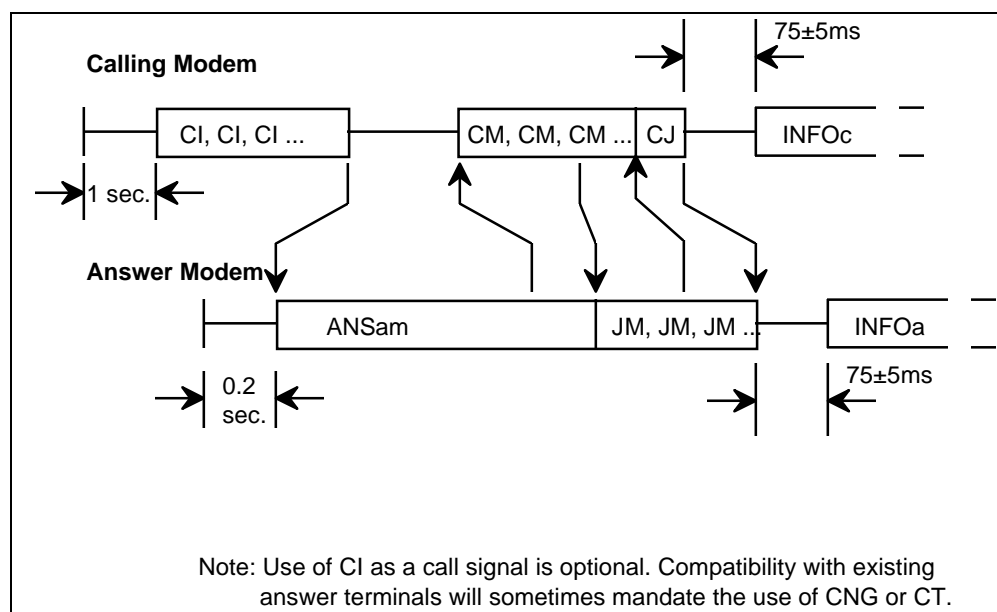

Figure 17-2. V.8 Procedures - Phase 1 Exchange

After 75 ± 5 ms of silence, Call Modem sends the INFOc sequence followed by Tone B (1200Hz) with phase reversals (/B). The Answer Modem sends INFOa sequence followed by Tone A (2400 Hz) with phase reversals (/A).

All INFO sequences are sent using DPSK at 600 bps with the split band.

The INFO sequence contains: supported symbol rates, carrier frequency capability, transmit power reduction capability, maximum difference in symbol rates between TX and RX paths, transmit clock source.

After detecting the Tone A phase reversal, the Call Modem continues to transmit Tone B for another 40 ms and then transmits a Tone B phase reversal for 10 ms.

Next, the Call Modem transmits L1 and L2 line probing signals as defined in V.34. These signals are sets of probing tones with the repetition rate 150 Hz and spacing 150 Hz. At the end of this phase Answer Modem sends the INFOh sequence -- Frame Sync, minimum transmit power, length of TRN to be transmitted, carrier frequency, pre-emphasis filter requested, symbol rate, etc. The Phase 2 procedures are shown in Figure 17-3.

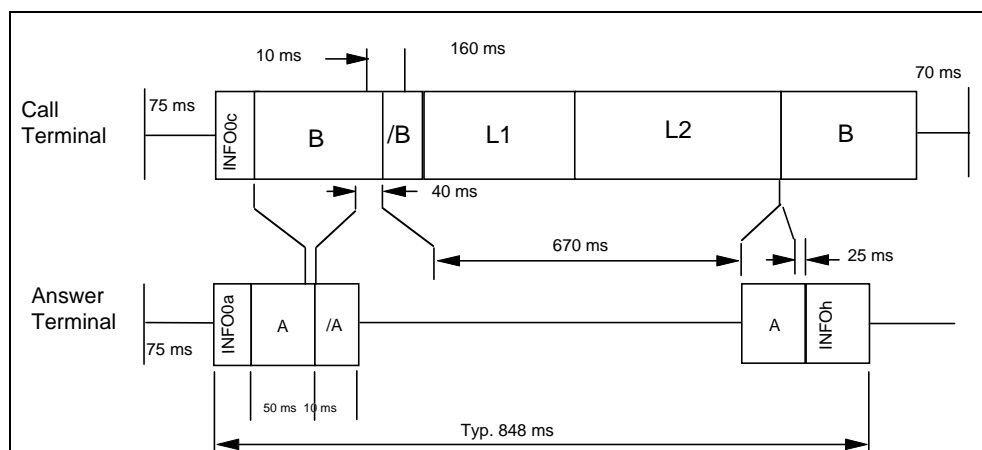

Figure 17-3. V.34 Line Probing (Phase 2)

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Figure 17-4 shows Phase 3 V.34 HDX training. All signals are transmitted using the selected symbol rate, carrier frequency, pre-emphasis filter, and power level. This half-duplex training procedure is used to train the equalizer. All signals: S, /S, PP and TRN are defined in V.34 and are using the V.34 modulation. The constellation size and duration of TRN are set according to the INFOh sequence received from the recipient modem.

Figure 17-4. V34 HDX Training Procedure (Phase 3)

Phase 4 (Figure 17-5) is a control channel start-up and is used for final parameter exchange in the V.34 HDX handshaking. PPh is used in half-duplex mode for control channel receiver initialization and resynchronization. Modulation Parameter Sequences are exchanged between modems and contain modulation parameters to be used for the data transmission. The MPh symbols are transmitted using the control channel modulation at 1200 bps. At the end of this phase both modems send the E sequences to signal the beginning of control channel user data. It uses the control channel modulation at 1200 bps.

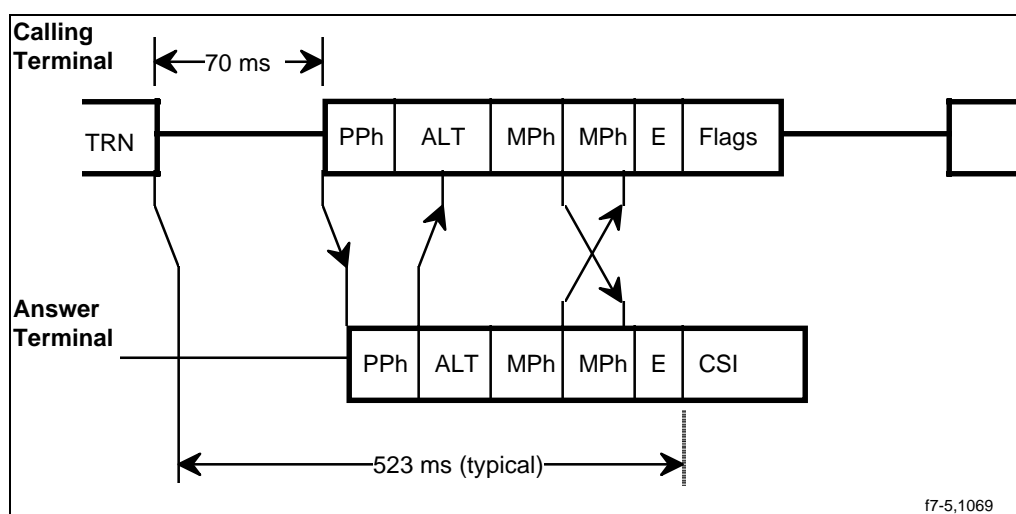

Figure 17-5. V34 Parameter Exchange

In Phase 5 both modems start the basic T.30 handshake using the control channel modulation at 1200 bps in a pseudo half-duplex fashion. The T.30 handshaking procedure is shown in Figure 17-6. (Phase 6 is the image data transmission phase.)

After the source modem transmits the image data using the primary channel (PC), it transmits the turn-off sequence followed by 70 ± 5 ms of silence. After this both modems go to control channel. Basically this exchange can be divided into two parts: Page confirmation using the control channel (and T.30 procedures), and V.34 HDX resync. The procedure between pages is shown in Figure 17-7.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

The PC turn-off sequence (Figure 17-7) consists of a 35 ms transmission of “scrambled ones”. At the end of the CC channel—after receiving CFR, MCF or other post message response—the source terminal will transmit consecutive “1”s until silence is detected from the recipient terminal and at least 40 ones have been sent.

Figure 17-6. T.30 Fax Handshaking (Phase 5)

Figure 17-7. Inter-Page Procedure

17.2 START-UP SCENARIOS

All fax machines implementing V.34 Fax ability must preserve the compatibility with existing traditional fax machines. To support existing fax machines, all fax start-up scenarios must be considered.

Four basic types of start-up scenarios (two automatic and two manual) are described below.

Automatic start scenarios:

- Error free
- With errors

Manual start scenarios:

- Error free
- With errors

There are three interoperability cases:

- Call modem is V.8; Ans modem is V.8
- Call modem is V.8; Ans modem is V.21
- Call modem is V.21; Ans modem is V.8

Definitions:

- V.8 terminal refers to a terminal with V.8 ability enabled. This includes transmitting ANSam when answering a call.
- V.21 terminal refers to a traditional T.30 terminal that does not have V.8 ability or does not have V.8 ability enabled.

17.2.1 Automatic Start Scenerios

Error-free Automatic Start

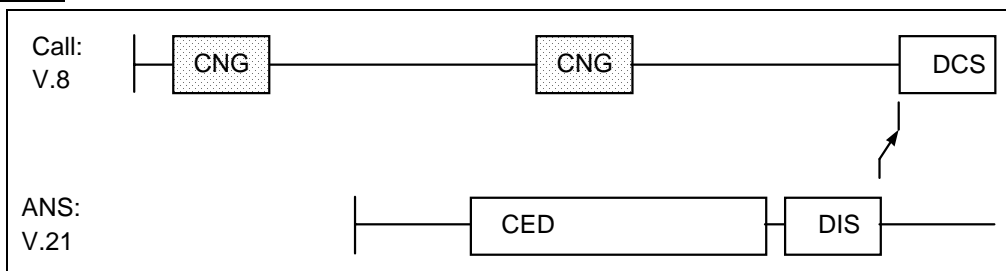

There are 3 primary cases for error-free v.8 startup when both terminals are configured in automatic mode:

Call: V.8, ANS: V.8

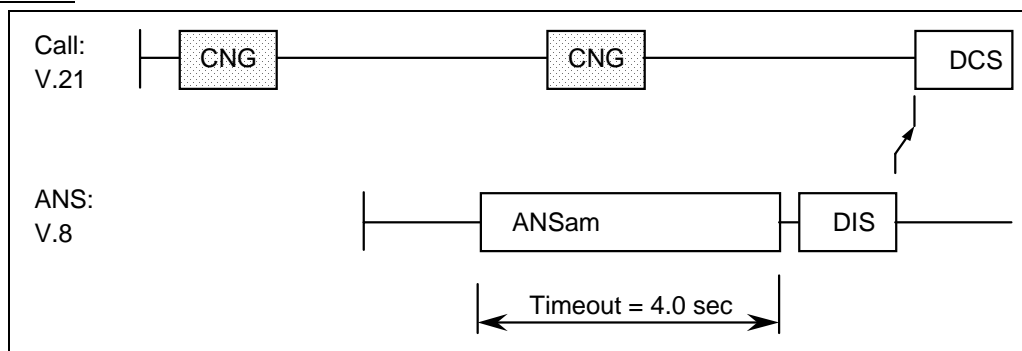

Note that the originate and answer modems (that is, direction of half duplex line probing) depends on the Call Function octet of V.8. The typical case is Call Function 4 (b5=0, b6=0, b7=1) where the line probing tones are sent from the call modem because the call modem is transmitting a fax to the answer modem. In the initial polling case (Call Function 5, b5=1, b6=0, b7=1), the line probing tones are sent from the **Answer** modem since the call modem wants to **receive** a FAX.

Call: V.8, ANS: V.21

Call: V.21, ANS: V.8

Automatic Start with Errors

Call: V.8, ANS: V.8

- If ANSam is completely missed, there is no recourse on the call side. Caller should try to detect DIS.
- If ANSam is interpreted as CED, the answer modem will still have DIS bit 6 set so a "manual type" V.8 startup call will still lead to a V.8 negotiation.
- If CM is missed, V.8 section 8.2.2/V.8 paragraph 4 indicates ...continue as in T.30. Since CM was not received in response, the answer modem should send DIS and have bit 6 set even though it would appear that the other terminal is not V.8 capable since it did not respond to ANSam.
- If JM is missed or 2 identical JM sequences have not been received, no error recovery is defined in V.8 on the call side. The answer side continues to send JM (because it would not receive the JM terminating CJ) and can terminate using its own criteria (8.2.3/V8 paragraph 2) and then possibly transmit DIS. The call side must be prepared to detect JM and V.21H (DIS).

Call: V.8 -> ANS: V.21

- If CED is missed, no problem since CED is optional.
- If DIS is missed, DIS is repeated as per T.30.

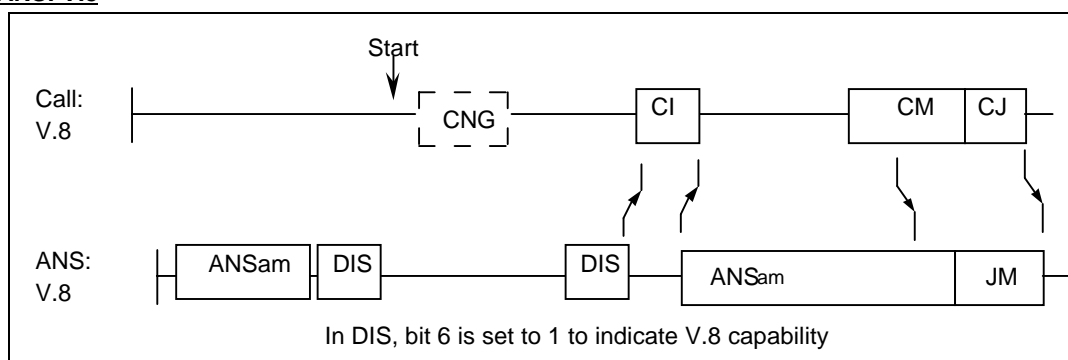

Call: V.21 -> ANS: V.8

- If ANSam is missed, no problem since CED (as ANSam) is optional.
- If DIS is missed, DIS is repeated as per T.30.

17.2.2 Manual Start Scenarios

Error-Free Manual Start - Sending

Call V.8 -> ANS: V.8

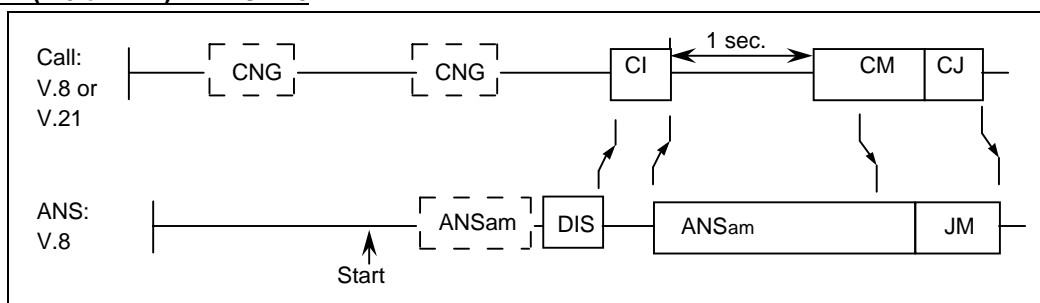

Call V.8 -> ANS: V.21

Call starts with optional CNG and is set to detect V.21. Since bit 6 will be set to 0, Call modem will proceed with original type negotiations using V.21.

Error-Free Manual Start - Receiving

Call: Unknown (V.8 or V.21) -> ANS: V.8

Call: Unknown (V.8 or V.21) -> ANS: V.21

Proceed as in existing T.30.

Manual Start with Errors

Call V.8 -> ANS: V.8

- If CNG is missed or, optionally, not sent, DIS should continue to be transmitted as per the existing T.30 state.
- If DIS is missed, DIS should automatically repeat if it does not receive any response.
- If CI is missed, DIS should repeat.

The rest of the error cases are the same as the automatic scenarios.

Call V.8 -> ANS: V.21

Proceed as in existing T.30. (DIS repeats until response received.)

Manual Receive with Errors

Call: Unknown (V.8 or V.21) -> ANS: V.8

- If DIS is missed, CNG will, optionally, continue to repeat. DIS will continue to repeat while waiting for a response.
- If CI is missed, DIS will continue to repeat.
- If ANSam is completely missed, there is no recourse on the call side. (Per section 7.2/V.8 paragraph 4, "A call DCE shall not transmit a signal CM unless ANSam has been detected."). Caller should try to detect DIS.

Call: Unknown (V.8 or V.21) -> ANS: V.21

Proceed as in existing T.30.

17.3 TURNAROUND POLLING AND SCENARIOS

Turnaround polling involves changing the direction of fax transmission. Since the direction of the high data rate will be reversed, network providers need to be informed of this change through V.8 type means, so that they can reconfigure demod/remod equipment if necessary.

Traditional V.8 will not send CM until ANSam is detected but in the turnaround polling cases, transmission of CM will commence the "V.8" exchange even though an ANSam signal will not be sent by the answer modem.

17.3.1 Changing from Transmit to Receive Fax

Figure F.5.11/T.30 illustrates the case of a call terminal transitioning from transmitting a fax to receiving a fax. Immediately after receiving forty "1"s from the recipient modem, the calling modem turns off the control channel by turning DTR off, waits 70 ± 5 ms, and then initiates a V.8-like exchange by transmitting CM.

17.3.2 Changing from Receive to Transmit Fax

Figure F.5.12/T.30 illustrates the case of a call terminal transitioning from receiving a fax to transmitting a fax. As in the typical transition into the primary channel, the source (call) modem will transmit "1"s and will wait for the recipient modem to turnoff. Then the source modem will turnoff its control channel, transmit silence for 70 ± 5 ms and then transmit CM.

17.4 SUMMARY OF SIGNAL DETECTORS AT EACH PHASE

17.4.1 Call Terminal

During transmission of (optional) CNG, need to detect:

- ANSam (Auto, Error-free, V.8 -> V.8)
- CED (ANS) (Auto, Error-free, V.8 -> V.21)
- DIS (V.21(H)) (Manual, Error-free, V.8 -> V.8/V.21) since CED is optional in the manual receive case.

During transmission of CI, need to detect :

- ANSam (Manual, Error-free, V.8 -> V.8)
- DIS (V.21(H)) (Error, V.8 -> probable V.8)

During transmission of CM need to detect :

- ANSam (Manual, Error-free, V.8 -> V.8)
- JM (Error-free, V.8 -> V.8)
- DIS (V.21(H)) (Error: answer missed CM)

17.4.2 Answer Terminal

During transmission of ANSam, need to be able to detect:

- CM (Auto, Error-free, V.8 -> V.8)
- CNG (Auto, Error-free, V.21 -> V.8)

During transmission of DIS (with bit 6 set) must be able to detect and receive:

- CI (V.21(L)) (Manual, Error-free, V.8 -> V.8)
- DCS (V.21(H)) (Manual, Error-free, V.21 -> V.8)

During turnaround polling, need to be able to detect:

- CM (Auto, Error-free,)

17.5 OPERATION AND CONNECTION

The host can access several registers in RAM to control and monitor V.8 operation. There are five control registers (Table 17-1) and three status registers (Table 17-2). The host also has access to registers that contain the configuration (CONF) codes associated with the modulation modes of operation (Table 17-3).

To enter V.8 mode, load the interface memory CONF register with AAh and then set the NEWC bit. Negotiation begins when DTR is set by the host.

For V.34 Half Duplex (HDX) modes, different operating procedures are required. The host can access several registers in RAM to control and monitor V.8 and V.34 operations. There are 5 control registers (Table 17-1) and three status registers (Table 17-2). The host also has access to registers that contain the configuration (CONF) codes associated with the modulation modes of operations.

17.5.1 Configuration and Operation Setup

Configuration Selection

To enter V.8 the host must do the following:

1. Write the AAh code corresponding to the desired mode to the CONF register.
2. Set or reset any control bits to the state desired at the beginning of the selected mode.
3. Set ScratchPad bit ORG in the source modem and reset ORG in the recipient modem.
4. Set addresses 304h = 88h and 306h = 80h for V.34 HDX operation.
5. Set the NEWC bit to initiate the new configuration.
6. Set the DTR bit to start the V.8 handshake for V.34 half-duplex mode.

If DTR is cleared by the host, the modem terminates the connection and enters idle mode.

V.34 Half Duplex Modem Operation

For V.34 Half Duplex Control and Primary Mode Operation

The host should not set RTS before or during the V.34 training. The modem will automatically enter control channel mode and begin sending HDLC flags (The host of the source modem sets RTS to 1 when it desires to enter the primary channel mode. The host of the recipient modem should not change the status of RTS)

V.34 Half Duplex Source Modem Operation

1. Transmit control channel data
2. Wait until the CTS, TDBE, and FLAGS bits are set (RTS is still off) before attempting to load data to be transmitted via the control channel.
3. Write the (control channel) byte to transmit to TBUFFER.
4. Continue to load (control channel) data in TBUFFER each time the TDBE bit is set until the data transfer is complete.
5. Receive control channel data. (simultaneously with 1.)
6. Wait until the RLSD and SYNCD bits are set and the RDBF bit is set.
7. Read the 7E (Flag) data byte from RBUFFER.
8. Once the receive process is activated, the modem enters acquisition mode. Received (control channel) data may be read from RBUFFER when ever RDBF or RXFNE is set.
9. If the source host wishes to initiate a control channel retrain, bit 06h:5 (CCRTN) should be set.
10. The host should then set RTS to indicate desire to transmit via the Primary channel Mode.
11. Transmit primary channel data
12. Wait until the CTS, TDBE, and FLAGS bits are set before attempting to load data to be transmitted by the primary channel.
13. Write the (primary channel) byte to transmit to TBUFFER.
14. Continue to load (primary channel) data in TBUFFER each time the TDBE bit is set (or if TXFNF is set) until the data transfer is complete.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

15. If the host desires to change the data rate of the next primary channel or control channel session, the host must set the configuration to the desired new rate before RTS is turned off. To change the primary channel data rate, the host writes the new rate to CONF. To change the control channel data rate, the hosts configures bits CC and possibly 3DFh[6] (see CC bit description).
16. If the host wishes to return to Control Channel Mode, the host should reset RTS and proceed as from step 1.

V.34 Half Duplex Recipient Modem Operation

1. Transmit control channel data
2. Wait until the CTS, TDBE, and FLAGS bits are set (RTS is still off) before attempting to load data to be transmitted via control channel.
3. Write the (control channel) byte to transmit to TBUFFER.
4. Continue to load (control channel) data in TBUFFER each time the TDBE bit is set until the data transfer is complete.
5. Receive control channel data (simultaneously with 1)
6. Wait until the RLSD and the RDBF bits are set.
7. Read the 7E (Flag) data byte from RBUFFER.
8. Once the receive process is activated, the modem enters acquisition mode. Received (control channel) data may be read from RBUFFER when ever RDBF or RXFNE is set.
9. If the recipient host wishes to initiate a control channel retrain, bit 06h:5 (CCRTN) should be set.
10. When the host detects CTS turned off, any remaining control channel data should be read from RBUFFER. (The modem will automatically reset CTS and initiate the turn off sequence of the recipient modem control channel transmitter when it has received forty consecutive ones from the source modem.)
11. Receive primary channel data
12. Wait until the RLSD and SYNCD bits are set and the RDBF bit is set.
13. Read the 7E (Flag) data byte from RBUFFER.
14. Once the receive process is activated, the modem enters acquisition mode. Received (primary channel) data may be read from RBUFFER when ever RDBF or RXFNE is set.
15. If the host desires to change the data rate of the next primary channel or control channel session, the recipient host must set the configuration to the desired new rate before RTS is turned off in the source modem. To change the primary channel data rate, the host writes the new rate to CONF. To change the control channel data rate, the hosts configures bits CC and possibly 3DFh[6] (see CC bit description).
16. When the host detects RLSD turns off, any remaining primary channel data should be read from RBUFFER.
17. The host should now prepare for control channel data as per step 1.

HDLC Operations

In control channel mode, parallel data HDLC is forced even though ScratchPad bits TPDM and HDLC are not set by the modem. The host may turn off HDLC by setting 3C9h[7] = 0 after the control channel has entered data mode. If the source modem sends a string of 40 binary 1's and the recipient modem detects it, the recipient modem will automatically exit control channel mode.

17.5.2 Originating Modem Operating Procedure

Originating modem negotiation procedures may be started by sending CNG or CI (CI will be sent if the host sets register 304 bit 2 while in V.8 mode).

Originating with CNG

The basic automatic-to-automatic origination procedure is shown in Figure 7-8. Some of the configuration details are shown in Figure 17-9.

After dialing, Figure 17-8 shows monitoring bit ATV25 (0B:4) to detect ANS (CED) or ANSam and FLAGDT (0A:6) to detect V.21 Flags. If ATV25 is set, to discriminate between CED and ANSam, configure and initiate V.8 by setting CONF = AA, set NEWC, and then set DTR.

In (V.8) originate mode, the transmitter is set up to transmit Silence by default (38Fh:3 = 0 and 304h:2 = 0). The receiver is set up to detect ANS and ANSam. The data pump sets register 301 bit 5 when ANS is detected and register 302 bit 3 if ANSam is detected. In the case of ANSam signal, the ANS bit will be set before the ANSam bit. The bit turn on timing depends on the line conditions and receive levels.

If ANS only (i.e., CED) is detected, V.8 mode is stopped by turning DTR off and then prepare to receive V.21 signals by setting CONF = A8 and proceed.

Once ANSam is detected, the transmitter waits a silence period before transmitting CM. The silence period is 500 ms if no phase reversals are detected in ANSam, otherwise the silence period is 1 second. The CM sequence consists of a Preamble, followed by a SYNC octet, a Data Call Function Category octet, at least one modulation mode octet, an optional protocol octet, and an optional GSTN octet. The 16-byte transmit buffer, located at address 32D, is loaded with the CM sequence once ANSam is detected.

The number of modulation mode octets transmitted is a function of the bit settings in control registers 306 to 308 (Table 17-1). For example, if no modulation bits are set in registers 307 or 308, then only one modulation octet is sent (modn0). On the other hand, if bits are set in register 307, but not in register 308, then modn0 and modn1 are sent. Only when register 308 contains non-zero modulation bits will all three modulation octets be sent.

The protocol octet is transmitted if register 305 bit 0 is set. The 3-bit protocol field is located in register 305 bits 5-7. The default protocol bits are set to indicate LAPM availability. The GSTN octet is sent if address 304 bit 4 is set. The GSTN octet will be sent indicating cellular access if address 305 bit 2 is set.

CM transmission continues until JM is detected. When JM is detected, the current CM octet is completed and then CJ is appended to the transmitted data stream. A 75 ms silence period follows CJ transmission and the CONF register is updated to the "Modulation Mode" indexed by the highest common modulation mode in JM (Table 17-2). If no modulation modes are common, the CONF register changes to C0h, the "V.8 Cleardown" mode.

Originating with CI

In some cases of delayed or manual start, an originating modem may not receive an ANSam signal but it does receive a V.21 DIS frame with bit 6 (V.8 capability) set to 1. The call modem should then prepare to send CI by setting CONF = AAh and 304h:2 to 1.

Once DTR transitions on, the transmitter is silent for 400 ms before the CI sequence is transmitted. CI is sent with a regular cadence of 1 second on and 1 second off. The on and off times are accessible via memory access. In particular, the on time counter, MaxFrameByteCount, is located at 31Ch. This counter is a "byte" counter and defaults to 30 bytes for CI transmission. (Note that the MaxFrameByteCount should not be less than 9 (= 3 frames) if the minimum three frames of CI is desired.) If this location is negative (i.e., MSB = 1), then there is no cadence applied to the transmitted V.8 frame.

Note: MaxFrameByteCount = FFh when transmitting CM and JM.

The CI cadence will continue until ANSam is detected and the minimum three CI frames have been transmitted. Upon detection of ANSam, CM is sent in the manner described earlier in this paragraph.

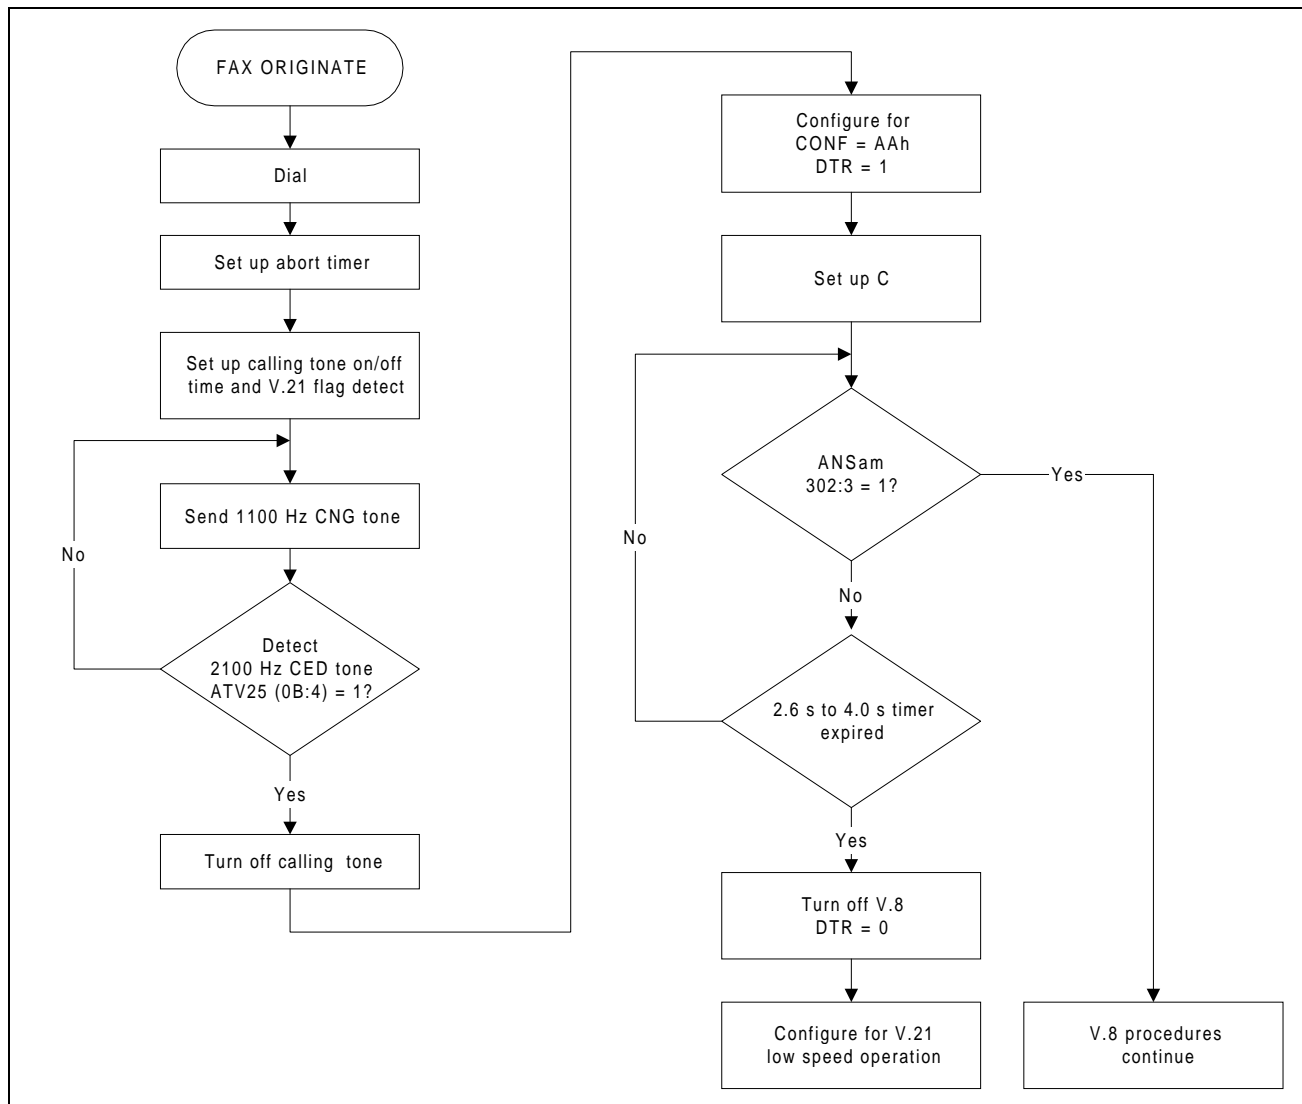

Figure 17-8. Automatic to Automatic Origination and Operation

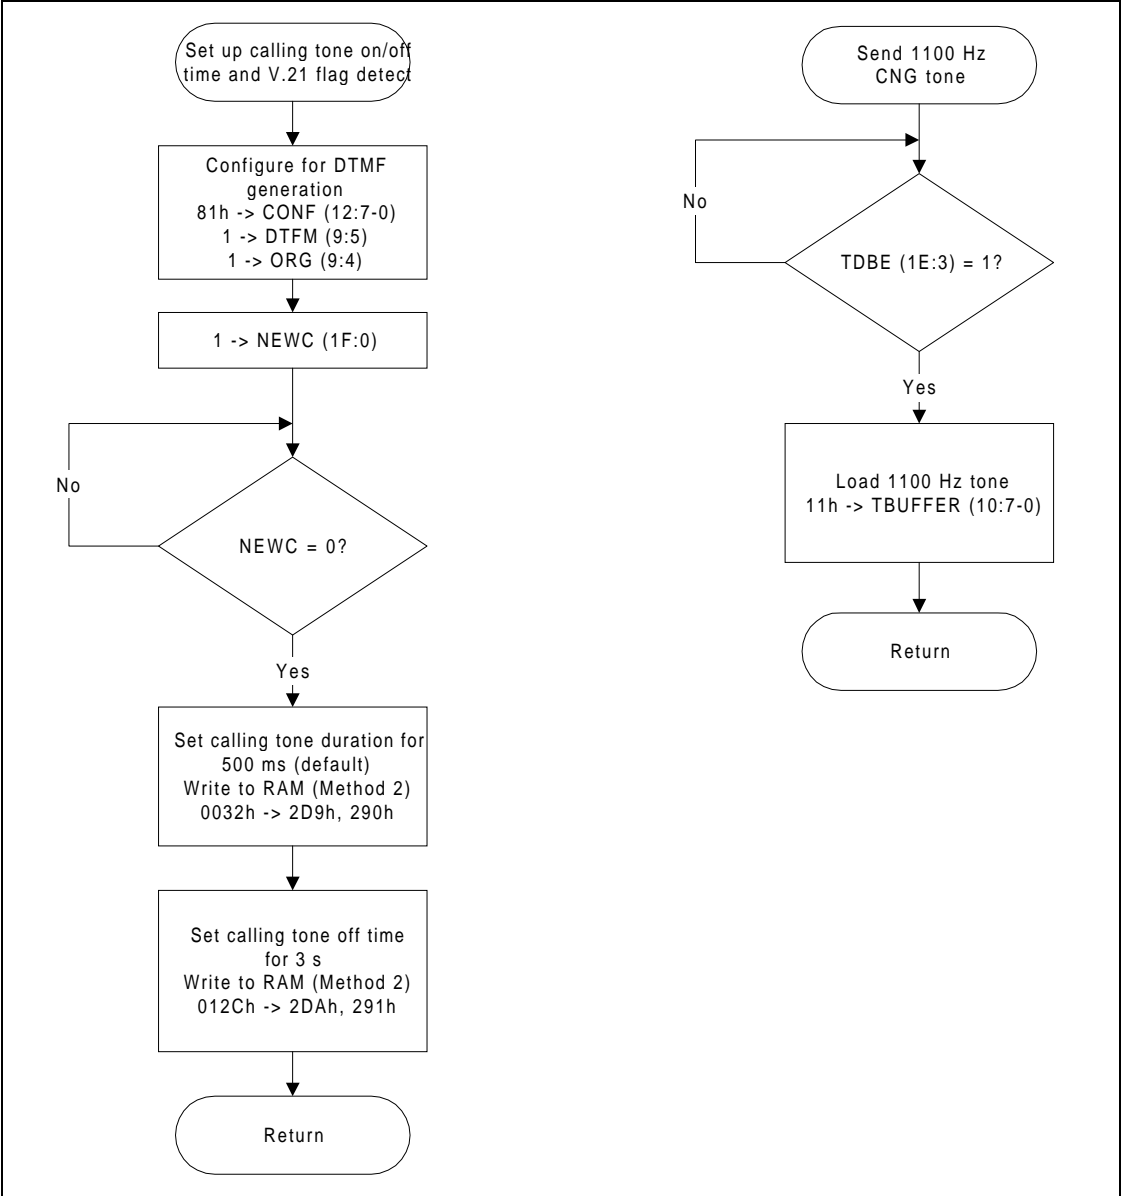

Figure 17-9. Configuration Procedures

17.5.3 Answering Modem Operating Procedure

General Procedures and Automatic Start

After the host goes off-hook, it configures the modem to send a V.8 ANSam answer tone. The caller may be another V.8 machine or an original V.21 only terminal, one of the following 2 paths (following paragraph) will need to be followed depending on the calling modem's response to ANSam.

When configured as the V.8 answer modem, the modem will transmit ANSam if 38Fh:3 = 0 and 304h:1 = 0. The host can monitor when the modem begins transmitting ANSam by observing 300h:0; when set the modem has begun transmitting ANSam. The modem does not reset 300h:0 when transmission of ANSam is completed. The host should initiate a 2.6 to 4.0 second timer when the modem begins transmitting ANSam, if the originate modem does not respond to ANSam with CM, the host should reconfigure for V.21 transmission (see below). The receiver will detect V.8 frames CI, CM, and CJ. Register 301 bits 1-3 hold the status of CM, CI, and CJ detection (see Table 17-2). If CM was detected, continue with Section 7.5.2.

V.21 only, Manual V.8, or Late Start

If no V.8 frames are detected, and the 2.6 to 4.0 second timer has expired, the host should prepare the modem to transmit V.21 and send a DIS frame with bit 6 set to indicate V.8 capability. The host shall turn off DTR, set CONF = A8, set NEWC, set RTS after 75±5ms, and transmit (NSF)DIS frames. Immediately after the DIS frame is transmitted, the host shall reconfigure the modem in V.8 and set 304h:1 to have the modem not transmit ANSam until after CI is received. The host should also program one of the Supervisory Tone Detectors to detect V.21 flags from a possible DCS frame coming from the call modem.

If V.21(H) flags are detected, the modem should be configured for V.21(H) operation (CONF=A8h) and the original T.30 procedures followed. If CI is detected, the modem will send ANSam and proceed with a V.8 negotiation.

V.21(H) Flag Detection during V.8

This subsection describes how to configure any of the three Supervisory tone detectors to detect V.21 High Channel HDLC Flags. This detector complements the FLAGDT bit, which does not run in V.8 modes. This is due to the architecture of the V.8 receiver. However by implementing this tone detector, a host can detect the appearance of FLAGS in V.8 modes.

Using the same naming convention as is defined in Function 27-29, the tone detector coefficients are:

	BIQUAD #1	BIQUAD #2
A3	0666h	0666h
A2	FFDDh	1C04h
A1	0666h	0666h
B2	0F71h	FEA2h
B1	C146h	C289h
THRESHU		2000h
THRESHL		2000h

The threshold values will require tuning to the hosts particular requirements, but a suggested value of 2000h in both Upper and Lower Thresholds (i.e., no hysteresis) is a reasonable starting point.

V.21(L) Flag Detection during V.21(H)

This paragraph describes how to configure any of the three Supervisory tone detectors to detect V.21 Low Channel (Bandpass filter 980-1180 Hz, stopband better than -40 dB, sample rate 7200 Hz).

Using the same naming convention as is defined in Function 27-29, the tone detector coefficients are

	BIQUAD #1	BIQUAD #2
A3	0D11h	0D11h
A2	E5F7h	0D11h
A1	0D11h	0D11h
B2	CC29h	CE1Ah
B1	5175h	3430h
THRESHU		0010h
THRESHL		0001h

After V.8 is started (CM detected)

When CM is detected, a JM frame is constructed using parameters from CM. The JM sequence starts with the 10 ONES preamble followed by the synchronization octet. Next comes the call function. If the received CM octet contains the same call function as the answer modem's "preferred" call function (register 304 bits 5-7), then the same call function that was received in CM is also sent in JM.

If the CM octet contains a different call function than the "preferred" call function, then the CallFunctionAllowed register (address 32A) is consulted (see Table 17-4). The host can set up the CallFunctionAllowed register to indicate the call functions that it allows. It is a bit-mapped register where an appropriate bit is set if corresponding call function is to be allowed. If the call function received in CM does not match any allowable call functions, then the preferred call function is returned with all modulation bits set to zero. On the other hand, if the call function is allowed, the answer modem will respond with the same call function as that received in CM.

JM will contain all the necessary modulation octets needed to reflect the jointly common modulation modes available at the answer modem and received in the CM sequence. If, however, address 305 bit 1 is set, then JM will contain the minimum number of modulation octets needed to convey the highest common mode. If no modulation modes are common, then the JM frame will send all modulation octets with none of the modulation bits set.

The protocol octet is sent only if the received CM contained a protocol octet AND control register 305 bit 0 is set. The GSTN octet is sent if control register 304 bit 4 is set OR if the received CM contained a GSTN octet. The GSTN octet will be sent indicating cellular access if control register 305 bit 2 is set.

If V.34 Half Duplex is negotiated, the modem will automatically continue with the V.34 startup procedures.

If V.17, V.29, or V.27 are negotiated, the host shall turnoff DTR (ending V.8) and proceed with configuring the modem for V.21 channel 2 (low speed) operation.

RP56LD/RP336LD and RP56D/RP336D Modem Data Pumps Designer's Guide

Table 17-1. V.8 Host Control Registers

Address (Hex)	7	6	5	4	3	2	1	0	Default Value (Hex) ¹
304	Call Function to be Transmitted			Send GSTN Octet	No PN+ID with ANSam	Transmit CI	No TX of ANSam until CI Detected	X	C0
305	Protocol Bits to be Transmitted			X	No RLSD in V.8	Cellular Access	Send Minimum JM Sequence	Send Protocol Octet	08
306	V.34 HDX	V.34 FDX	X	X	X	X	X	X	40
307	V.27	V.29	X	X	X	V.17	V.22	V.32	03

303	Received Protocol Bits						Remote is using Cellular	Received GSTN Octet	00

* Cleared on NEWC with CONF = AAh.

Table 17-3. Modulation Modes

Address (Hex)	Configuration	Default Value (Hex) ¹
30A	V.34 half duplex - 28.8kbps	CC
30D	V.17 (Note 3)	B1
30E	V.29 (Note 3)	14
30F	V.27 (Note 3)	02
312	V.23 full-duplex (Note 2)	A4
313	V.23 half-duplex	A4
314	V.21	A0

Notes:

- See CONF codes in Table 3-1.
- Default value assumes V.23 answer mode; change to A1 for V.23 originate mode (see CONF bits in Table 3-1).
- The default configuration of the modes may be changed to A8 (V.21 channel 2) so that the modem will automatically configure itself for V.21 channel operation immediately after V.8. The answer terminal host must set RTS 70 ± 5 ms after V.8 is complete.

32A	CF 7 Allowed (extension)	CF 6 Allowed (Duplex data) b7=1 b6=1 b5=0 oct=C1h	CF 5 Allowed (FAX-RX) b7=1 b6=0 b5=1 oct=A1h	CF 4 Allowed (FAX-TX) b7=1 b6=0 b5=0 oct=81h	CF 3 Allowed	CF 2 Allowed (V.18)	CF 1 Allowed	CF 0 Allowed	40h

17.5.4 Operation during Turnaround Polling

Following description refers to Figure F.5.11/T.30.

TX to RX

Call Terminal

Once the modem has detected at least forty "1"s, the modem will set bit PNSUC. The host should read any remaining data in RBUFFER, reset bit PNSUC, and turnoff DTR. The host should set CONF=AA, set NEWC, and set the "CM without ANSam" bit (38Fh:3) to 1. The host must set DTR within 70 ± 5 m after DTR was reset.

Answer Terminal

After the host has successfully received the T.30 DTC signal, the host should set MHLd (07:0) to indicate that the modem should begin transmitting consecutive "1"s. When RLSD has turned off, the host should set CONF=AA, set NEWC, set the "CM without ANSam" bit (38Fh:3) to 1 and set DTR.

RX to TX

Call Terminal

After the host has successfully received the T.30 DTC signal, the host should set RTS to indicate that the modem should begin transmitting consecutive "1"s. When RLSD has turned off, the host should set CONF=AA, set NEWC, and set the "CM without ANSam" bit (38Fh:3) to 1. The host must set DTR within 70 ± 5 ms after RLSD was turned off.

Answer Terminal

When RLSD has turned off, the host should set CONF=AA, set NEWC, set the "CM without ANSam" bit (38Fh:3) to 1 and set DTR.

17.5.5 Operation during Initial Polling

Call Terminal

If the calling terminal wishes to allow standard transmit and initial polling, it must set the Call Function Allowed register 32Ah to 30h and set register 304h according to the preferred first function. If only initial polling is desired, set 32Ah = 20h and 304h = A8h.

Monitor the CM/JM exchange. If JM indicates RX-FAX, during the silence period, reset the ORG bit.

Answer Terminal

If the answer terminal wishes to do an initial polling as it's first call function, it should set 32Ah = 20h and 304h = A8h. Monitor the CM/JM exchange. If JM indicates RX-FAX, during the silence period, set the ORG bit.

17.6 HANDSHAKE MONITORING

17.6.1 Octet Monitoring

During the V.8 (Phase 1) procedure the received V.8 octets can be read from the interface memory RBUFFER register by clearing bit 305h:3 of the V.8 host control bits. The procedure is the same as accessing receive data during normal data mode.

17.6.2 V.34 Fax Handshake Phase Monitoring

During the V.8/V.34 handshake, the control channel data buffers display the “state” of the receiver (SECRXB) and the transmitter (SECTXB). Bits 5, 6 and 7 of these buffers indicate the phase of the handshake (see Table 17-5 and Table 17-6). Using the New Status (NEWS) function, an interrupt can be generated whenever a change occurs to SECRXB and SECTXB. The NEWS masks for these locations are 370h and 371h, respectively.

Table 17-5. Receiver Handshake Phase and States

Register (Hex)	7	6	5	4	3	2	1	0
16 SECRXB	Receiver Handshake Phase (See box below.)			Receiver Handshake State				

Bits 7-5 Receiver Handshake Phase.

Bit 7	Bit 6	Bit 5	SECRXB Value	Handshake Phase (ITU Specification)
0	0	0	0x	Phase 1 (V.8)
0	0	1	2x	Phase 2 (V.34)
0	1	0	4x	Phase 3 (V.34)
1	0	0	8x	Phase 4 (V.34), Phase 5 (T.30 handshaking)
1	0	1	Ax	Phase 6 (V.34)

Bits 4-0 Receiver Handshake Phase States.

Table 17-6. Transmitter Handshake Phase and States

Register (Hex)	7	6	5	4	3	2	1	0
17 (SECTXB)	Transmitter Handshake Phase (See box below.)			Transmitter Handshake Phase State				

Bits 7-5 Transmitter Handshake Phase

Bit 7	Bit 6	Bit 5	SECTXB Value	Handshake Phase (ITU Specification)
0	0	0	0x	Phase 1 (V.8)
0	0	1	2x	Phase 2 (V.34)
0	1	0	4x	Phase 3 (V.34)
1	0	0	8x	Phase 4 (V.34), Phase 5 (T.30 handshaking)
1	0	1	Ax	Phase 6 (V.34)

Bits 4-0 Transmitter Handshake Phase State

Complete contents of SECTXB and SECRXB during handshake phases are shown in Table 17-7.

17.6.3 Control Channel Retrain

To initiate a CC retrain, the initiating host shall set bit CCRTN. The modem will turn off the CTS and transmit the AC signal. The modem's receiver will be able to detect PPh. Figure 17-10 shows the retrain sequence of actions at the initiating and responding modems.

There are two very important timing uncertainties to consider for V.34 training/resync/retrain procedures and timing diagrams as shown above:

1. A path's Trip Delay (one way) and Round Trip Delay play a very important part in the duration of, and relationship among, the signals shown. Since every connection will have a different delay time (for example, 30ms on a local call, 300 ms on a satellite) signals like MPh, which are repeatedly transmitted until 2 identical MPh frames are received, will significantly vary the number of MPh frames that are transmitted.
2. The length of a signal can vary according to manufacturers and implementation. For example, the duration of ALT can be anywhere from 16T to 120T. Thus a given timing diagram might not be to scale.

SECRXB and SECTXB are mainly for information for the host. The host should not take timing information from those registers. Host control implementation strategies may be based on the following:

- CC Initiating modem: After setting CCRTN, set a timer (about 1-2 seconds) to check for the end of CC retrain. (CTS turning on indicates CC retrain complete.)
- CC responding modem: During the control channel, the host should monitor SECRXB and SECTXB, if it ever changes from 84h, then a CC retrain procedure is likely in progress. A timer should be set to make sure CTS is on again after 1-2 seconds.

The host can look at each and every state change, but there is not so much benefit in normal situations. If a procedure fails, it is helpful to take note of the SECRXB, SECTXB, and ABCODE values to diagnose the problem.
